Genetic Inheritance and Bayesian Networks

Sargur Srihari

srihari@cedar.buffalo.edu
Genetics Pedigree Example

• One of the earliest uses of Bayesian Networks
  – Before general framework was defined
• Local independencies are intuitive
• Model transmission of certain properties such as blood type from parent to child
Phenotype and Genotype

• Some background on genetics needed to model properly
• Blood type is an observable quantity that depends on the genetic makeup
  – Called a phenotype
• Genetic makeup of a person is called a genotype
DNA Basics

Genome has 46 chromosomes (22 are repeated plus XX and XY)

Single Chromosome: ~$10^8$ base-pairs
Genome: sequence of $3\times10^9$ base-pairs (nucleotides A,C,G,T)
Represents full set of chromosomes

Large portions of DNA have no survival function (98.5%) and have variations useful for identification

TH01 is a location on short arm of chromosome 11:
short tandem repeats (STR) of same base pair AATG
Variant forms (alleles) different for different individuals
Genetic Model

- Human genetic material
  - 22 pairs of *autosomal* chromosomes
  - One pair of *sex* chromosomes (X and Y)

- Each chromosome contains genetic material that determine person’s properties

- Locus: Region of chromosome of interest
  - Blood type is a particular locus

- Alleles: Variants of locus
  - Blood type has three variants: A, B, O
Independence Assumptions

- Arise from biology
- Once we know
  - Genotype of a person
    - additional evidence about other members of family will not provide new information about blood-type
  - Genotype of both parents
    - Determine what is passed to off-spring
    - Additional ancestral information not needed
- These independencies can be captured in BN for a family tree
A small family tree
BN for Genetic Inheritance

G: Genotype
B: Blood Type
Autosomal Chromosome

- In each pair,
  - Paternal: inherited from father
  - Maternal: inherited from mother
- Person’s genotype is an ordered pair \((X,Y)\)
  - with each having three possible values \((A,B,O)\)
  - there are nine values such as \((A,B)\)
- Blood type phenotype is a function of both copies
  - E.g., genotype \((A,O)\) blood type is A
  - \((O,O) \rightarrow O\)
CPDs for Genetic Inheritance

- **Penetrance Model** $P(B(c)|G(c))$
  - Probabilities of different phenotypes given person’s genotype
    - Deterministic for bloodtype

- **Transmission Model** $P(G(c)|G(p),G(m))$
  - Each parent equally likely to transmit either of two alleles to child

- **Genotype Priors** $P(G(c))$
  - Genotype frequencies in population
Real models more complex

• Phenotypes for late-onset diseases are not a deterministic function of genotype
  – A particular genotype may have a higher probability of a disease
• Genetic makeup of individual determined by many genes
• Some phenotypes depend on many genes
• Multiple phenotypes depend on many genes
Modeling multi-locus inheritance

- Inheritance patterns of different genes not independent of each other
- Need to take into account adjacent loci
- Introduce selector variables $S(l,c,m)$
  - 1 if locus $l$ in $c$’s maternal chromosome inherited from $c$’s *maternal grandmother*
  - 2 if locus inherited from $c$’s *maternal grandfather*
- Model correlations of variables of adjacent loci $l$ and $l'$
Use of Genetic Inheritance Model

• Extensively used in
  1. In genetic counseling and prediction
  2. In linkage analysis
Genetic Counseling and Prediction

• Take phenotype with known loci and observed phenotype and genotype data for individuals
  – to infer genotype and phenotype for another person (planned child)

• Genetic data
  – Direct measurements of relevant disease loci or nearby loci which are correlated with disease loci
Linkage Analysis

• Harder task

• Identifying disease genes from pedigree data using several pedigrees
  – Several individuals exhibit disease phenotype
  – Available data
    • Phenotype information for many individuals in pedigree
    • Genotype information for known location in chromosome
  – Use inheritance model to evaluate likelihood
  – Pinpoint area linked to disease to further analyze genes in that area
    • Allows focusing on 1/10,000 of genome
Sparse BN in genetic inheritance

- Allow reasoning about large pedigree and multiple loci
- Allow use of *model learning* algorithms to understand recombination rates in different regions and penetration probabilities for different diseases
