Cancellable Biometrics

CSE666

Faisal Farooq
Biometrics

- Measurable, verifiable and unique physical characteristic or behavioral trait of an individual
Modalities

- Finger Scan: 48.8%
- Facial Scan: 15.4%
- Hand Scan: 10.4%
- Middleware: 11.9%
- Keystroke Scan: 0.4%
- Iris Scan: 6.2%
- Signature Scan: 2.7%
- Voice Scan: 4.3%

Source: International Biometric Group, New York, NY; 1.212.809.9491
Applications

- Immigration and Border Security
  - points of entry, pre-cleared frequent travelers, passport and visa issuance, asylum cases

- Law Enforcement
  - criminal investigation, forensics, national ID, driver’s license, correctional institutions

- Access Control
  - institutional, government, and residential

- Social services
  - fraud prevention in entitlement programs

- Attendance Recording
  - replacement of employee cards, ID’s

- Payment Systems
  - ATMs and kiosks
Advantages

- **Convenience**
  - No passwords, pins to remember (and lose)

- **No Buddy-punching**
  - Proper attendance recording

- **No Double-dipping**
  - In Ontario, ~2 million more identities in the health system than the population of the province.

- **Non-repudiation**
  - "I did not do it"
Disadvantages

• Error-prone
  – FRR – legitimate user denied access
  – FAR – illegitimate user granted access

• Intrusive
  – Less social acceptance

• Security
  – Personal data adequately protected?

• Non-revocable
  – Once compromised, the biometric is lost forever
  – Cannot be revoked or reset

• Cross-Matching
  – Same biometric at different locations
  – User can potentially be tracked
## Security and Privacy Issues

<table>
<thead>
<tr>
<th>Attacks on the biometric</th>
<th>Attacks on the Authentication System</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Spoofing</td>
<td>• Replay Attack</td>
</tr>
<tr>
<td>– Fake biometric (gummy finger, face image)</td>
<td>– Injecting templates in input by circumventing sensor</td>
</tr>
<tr>
<td>• Tampering</td>
<td>• Substitution</td>
</tr>
<tr>
<td>– Altering feature sets to obtain high scores</td>
<td>– Replacing the template in the database</td>

</tr>
</tbody>
</table>
Challenges

• Biometric Variance
  – Samples from same user change with time
• Inconsistent Presentation
  – fingers placed differently, pressure applied
• Irreproducible Presentation
  – Glasses, moustache, cuts, bruises
• Imperfect Representation
  – Unordered, slight change in signal, sensors
• Biometric Matching
  – Score/probability based (0-1)
Securing Biometrics
Securing Biometrics

Original space \rightarrow \text{Hash space}
Comparison with plaintext

Avalanche Effect - input is changed slightly, the output changes significantly
Example

Rumplestiltskin

Secret

Drop chars at 2, 5, 7, 9, 12, 14

Can it be inverted to the secret?

Rmpetltkn

Can it be inverted to the secret?

Rmpetltkn

+ 

Rmpetltkn

Drop chars at 2, 5, 7, 9, 12, 14
Noisy Situation

Rmplestilskin

Secret

Drop chars at 2,5,7,9, 12,14

Rplsiskn

Rmpetltnk

Match ?
Properties

• **Repeatable**
  
  Different instances of the biometric sample from the same user should produce the same key

• **Security**
  
  The key has to be non-invertible. The key should not leak information about the template or the user
Properties

• Discriminability
  – Samples from different individuals should produce different keys

• Cancelability
  – Keys could be cancelled

• Reusability
  – Keys can be reissued easily
Secure Biometrics*

- **Security**
  - Less susceptible to security attacks
  - Compliance with privacy laws

- **Cancelability**
  - revoked if compromised
  - reissued easily

- **Anonymity**
  - Removing true identity from the biometric
  - No retention of original biometric

- **Multiplicility**
  - Use of single biometric for multiple accounts
  - Cannot be cross-verified or identified

*SCAM Properties – Farooq et al., 2007*
Existing Methods

• Philosophy I
  – Generate stable representation of biometrics
  – Use conventional security algorithms
  – Perform matching in encrypted domain

• Philosophy II
  – Cannot generate reproducible representations
  – Devise non-invertible transforms
  – Perform matching in new domain
Existing Methods

• Biometric Encryption (I)

• Fuzzy Schemes (I)

• Non-invertible Transforms (II)

• Others (I/II)
Biometric Encryption

• Key $K(B)$ linked with biometric $B$

• Same key released for a genuine attempt

• No key released for an impostor attempt
Biometric Key Binding

**Enrollment**
- Fingerprint
- Image Features
- Output
- Link
- Stored Template

**Verification**
- Fingerprint
- Image Features
- Output
- Retrieve
- Key

Soutar et al. ’98
Enrollment Soutar et al. '98
Verification Soutar et al. '98

\[ H_0(u) \xrightarrow{\text{Convolution}} c'(x) \]

\[ H_s(u) \xrightarrow{\text{Bioscrypt}} \]

\[ \text{Encrypt} \rightarrow \text{Hash} \rightarrow \text{ID} \]

\[ \text{Compare} \rightarrow \text{Output} \]
Biometric Encryption - example

**Enrollment**

Alice → PIN → Template → (Pub, Pri) → Bob

**Verification**

Alice → Template → PIN → Pri → (Rand) → Pub (Rand) → Bob
• Advantages
  – Actual biometric not stored
  – Key can be arbitrarily long (thus secure)
  – Key can be cancelled and re-issued

• Disadvantages
  – Hard to derive robust keys from noisy data
  – Key error-prone
  – Highly susceptible to distortion
  – If key is compromised, biometric not required
  – Incompatible with standard minutiae representation
Fuzzy Schemes

- Place a secret S in a vault
- Lock the vault using a biometric B
- Use Chaff points (noise bits) for security
- Unlock the vault using biometric B’
- Reproduce S from B’ iff \( d(B,B') < \varepsilon \)
Fuzzy Vault  

Juels and Sudan ’02, Clancy et al. ’03

Enrollment

\[ a_n u_n + a_{n-1} u_{n-1} + a_{n-2} u_{n-2} + \ldots + a_0 \]

Chaff Points

Polynomial Projection

Vault

Verification

\[ c_n u^*_n + c_{n-1} u^*_{n-1} + c_{n-2} u^*_{n-2} + \ldots + c_0 \]

Error Correction

Vault
• Advantages
  – Actual biometric not stored
  – Auxiliary information reduces intra-user variation

• Disadvantages
  – Error rates high
  – Alignment of query and template an issue
  – Not easy to regenerate
  – Revoking and reissuing not straightforward
Auxilliary Data

• Additional Data to facilitate alignment
  – Helper Data Systems  Tuyls et al. ’03, ’04, ’05
  – Orientation Field Flow Curves  Uludag and Jain ’06
Fuzzy Extractors  Dodis et al. '04

- Use polynomial of higher degree instead of chaff points
- Key is regenerated only if query and template are “close” to each other.
Biometric Hardening

• Reminiscent to ‘password salting’
Transforms

- Non-invertible transforms of biometrics
- Key-based and keyless systems proposed

\[ F_t(x) \rightarrow G_t(x) \]

Enrolment: \( F_t(x) \rightarrow T(k) \rightarrow G_t(x) \)

Verification: \( F_t'(x) \rightarrow T(k) \rightarrow G_t'(x) \)
Transforms

• Advantages
  – Compatible with standard representations
  – Security, Cancelability, Anonymity, Multiplicity

• Disadvantages
  – Some methods require registration
  – Key-less systems usually have low accuracies
Surface Folding  

Ratha et al. '07

\[ X' = x + K \cdot \vec{G}(x, y) + K \cos(\Phi_F(x, y)) \]

\[ Y' = y + K \cdot \vec{G}(x, y) + K \sin(\Phi_F(x, y)) \]

\[ \Theta' = \text{mod}(\theta + \Phi_G(x, y) + \Phi_{\text{rand}}, 2\pi) \]

Locally Smooth but not globally smooth
Surface Folding

• Advantages
  – Achieves cancelability, security and multiplicity
  – Compatible with standard minutiae based representations
  – Compatible with existing point-based matchers

• Disadvantages
  – Alignment of query and template is an issue
  – Assume stable points (core and delta) for alignment
  – Low Security
BioHashing  Teoh et al 2006

• Locally Smooth but not globally smooth

• Johnson-Lindenstrauss Lemma

For any $0 < \varepsilon < 1$ and any integer $n$, let $m$ be a positive integer such that

$$m \geq \frac{4 \log n}{\varepsilon^2 / 2 - \varepsilon^3 / 3}$$

Then, for any set $S$ of $n = |S|$ data points in $\mathbb{R}^p$, there is a map $f : \mathbb{R}^p \rightarrow \mathbb{R}^m$ such that for all $x, y \in S$

$$(1 - \varepsilon) \| x - y \|^2 \leq \| f(x) - f(y) \|^2 \leq (1 + \varepsilon) \| x - y \|^2$$

i.e. a set of $n$ points in high dimensional Euclidean space can be mapped down into a $O(\log n / \varepsilon^2)$ space such that the distance between the points changes only by a factor of $1 \pm \varepsilon$
Random Multispace Quantization

- Project biometric to a lower dimensional feature domain (PCA, LDA, FDA)
- Project onto multiple random subspaces derived from external input (key)
- Quantize these individual maps and match
• Advantages
  – Actual biometric not stored
  – Auxiliary information increases inter-user variation
  – Error rates low*
  – Easy to generate, revoke, reissue

• Disadvantages
  – Alignment of query and template an issue
  – Case when key and biometric both are stolen
Represent Minutia as complex numbers

$$z = x + yi = \sqrt{x^2 + y^2} \left( \frac{x}{\sqrt{x^2 + y^2}} + \frac{y}{\sqrt{x^2 + y^2}} i \right)$$

Denote $|z| = \sqrt{x^2 + y^2}$ - magnitude of $z$

Then

$$z = |z| \left( \frac{x}{|z|} + \frac{y}{|z|} i \right) = |z| (\cos \theta + i \sin \theta)$$
Transformation of minutiae set.

\[ f(z) = rz + t \]

Multiplying by \( r \) means rotating by angle \( \phi \) and scaling by factor \( |r| \).
Hash functions of minutia points

Consider following functions of minutia positions:

\[ h_1(c_1, c_2, \ldots, c_n) = c_1 + c_2 + \ldots + c_n \]
\[ h_2(c_1, c_2, \ldots, c_n) = c_1^2 + c_2^2 + \ldots + c_n^2 \]
\[ \vdots \]
\[ h_m(c_1, c_2, \ldots, c_n) = c_1^m + c_2^m + \ldots + c_n^m \]

The values of these symmetric functions do not depend on the order of minutia points.
Hash of transformed minutiae

What happens with hash functions if minutia point set is transformed?

\[
h_1(c'_1, c'_2, \ldots, c'_n) = c'_1 + c'_2 + \ldots + c'_n
\]
\[
= (rc_1 + t) + (rc_2 + t) + \ldots + (rc_n + t)
\]
\[
= r(c_1 + c_2 + \ldots + c_n) + nt = rh_1(c_1, c_2, \ldots, c_n) + nt
\]

\[
h_2(c'_1, c'_2, \ldots, c'_n) = c'_1^2 + c'_2^2 + \ldots + c'_n^2
\]
\[
= (rc_1 + t)^2 + (rc_2 + t)^2 + \ldots + (rc_n + t)^2
\]
\[
= r^2(c_1^2 + c_2^2 + \ldots + c_n^2) + 2rt(c_1 + c_2 + \ldots + c_n) + nt^2
\]
\[
= r^2h_2(c_1, c_2, \ldots, c_n) + 2rh_1(c_1, c_2, \ldots, c_n) + nt^2
\]
Finding transformation parameters

Thus \( h_i(c_1', c_2', \ldots, c_n') \) can be expressed as a linear combinations of \( h_j(c_1, c_2, \ldots, c_n) \), \( j \leq i \) with coefficients depending on transformation parameters \( r \) and \( t \).

Denote:
\[
\begin{align*}
  h_i & = h_i(c_1, c_2, \ldots, c_n) \\
  h_i' & = h_i(c_1', c_2', \ldots, c_n')
\end{align*}
\]

Thus
\[
\begin{align*}
  h_1' & = rh_1 + nt \\
  h_2' & = r^2 h_2 + 2 rth_1 + nt^2
\end{align*}
\]

And \( r, t \) can be calculated given \( h_1, h_2, h_1', h_2' \)
Configurations

- $n=2, m=1$: for each minutia point we find it nearest neighbor, and
  \[ h_1(c_1, c_2) = \frac{c_1 + c_2}{2} \]

- $n=3, m=1$: for each minutia point we find two nearest neighbors and
  \[ h_1(c_1, c_2, c_3) = \frac{(c_1 + c_2 + c_3)}{3} \]

- $n=3, m=2$: for each minutia point find three nearest neighbors, and for each minutia triplet including original minutia point construct 2 hash functions
  \[ h_1(c_1, c_2, c_3) = \frac{(c_1 + c_2 + c_3)}{3} \]
  \[ h_2(c_1, c_2, c_3) = \frac{(c_1 - h_1)^2 + (c_2 - h_1)^2 + (c_3 - h_1)^2}{3} \]
Security

• If the number of stored hash functions $h_i$ is less than the number of minutia points, it is not possible to find the positions of minutia points $c_j$ from local hash values.

• Using system of hash equations is difficult, since it is not known which minutia correspond to particular hash value.
• **Advantages**
  – No alignment of query and template required
  – Achieves cancelability, security
  – Compatible with standard minutiae based representations
  – Compatible with existing point-based matchers

• **Disadvantages**
  – Error Rates higher than many existing systems
  – Security for existing configuration
  – Multiplicity and reissuing
  – Scoring
Linear Representations  Farooq et al 2007

• Face representation in terms of Eigenfaces

• Iris representation as bit strings

• Can we devise a linear representation for fingerprints?
  – new way to construct anonymous fingerprint representations
  – representation invariant to transformation (translation/rotation)
Motivation

• Minutiae triplets form triangles

• Fingerprint can be linearly represented as a set of triangles

• The triangle geometry does not change under rigid transformation

• Multiple invariants can be associated with triangles
Invariant features

- **Independent triangle features**
  - The sides

- **Dependent triangle feature**
  - Height at largest side

- **Fingerprint features**
  - Minutiae angles with respect to triangle

![Diagram of a triangle with labels](image)

\[
\begin{align*}
    a_1 & \\
    a_2 & \\
    a_3 & \\
    s_1 & \\
    s_2 & \\
    s_3 & \\

\end{align*}
\]

INDEX
Triangles can be enumerated

\[ \begin{align*}
1 & \\
2 & \\
. & \\
. & \\
. & \\
. & \\
. & \\
2^{(3 \times p)} & \\
\end{align*} \]

\[ = \]

\[ (s_1 \ s_2 \ s_3) \]

Impossible and possible triangles

\[ \begin{align*}
0 & \\
1 & \\
2 & \\
3 & \\
4 & \\
. & \\
. & \\
. & \\
. & \\
. & \\
. & \\
. & \\
2^{(3 \times p)} & \\
\end{align*} \]

\[ = \]

\[ (s'_1 \ s'_2 \ s'_3) \]

\[ s_1, \ s_2, \ s_3 \text{ quantized using } p \text{ bits} \]
Triangle Representations

- Triangle Indexing

Histogram
Matching

\[
\sum_{i=1}^{n} \frac{\min(F_i, \bar{F}_i)}{\sqrt{\sum_{i=1}^{n} F_i, \sum_{i=1}^{n} \bar{F}_i}} = \frac{3}{\sqrt{3 \times 4}} = 0.867
\]
• Advantages
  – No alignment of query and template required
  –Achieves cancelability, security
  –Compatible with standard minutiae based representations
  – Low Error Rates reported on very large sets
  – Multiplicity and reissuing very easy

• Disadvantages
  – Security for existing configuration ??
Conclusion

• Open area of research
• Increasingly gaining importance
• Process Biometric and use conventional (time tested) security techniques?
• Secure Biometric using new techniques?
