

Cancelable Biometrics

CSE666

Biometrics

- Measurable, verifiable and unique physical characteristic or behavioral trait of an individual

Security and Privacy Issues

Attacks on the biometric

- Spoofing
 - Fake biometric (gummy finger, face image)
- Tampering
 - Altering feature sets to obtain high scores
- Stealing
 - Acquiring the original template (database/network)

Attacks on the Authentication System

- Replay Attack
 - Injecting templates in input by circumventing sensor
- Substitution
 - Replacing the template in the database
- Overriding
 - Altering Yes/No response from system
- Trojan Horse
 - Replacing system component with malicious program

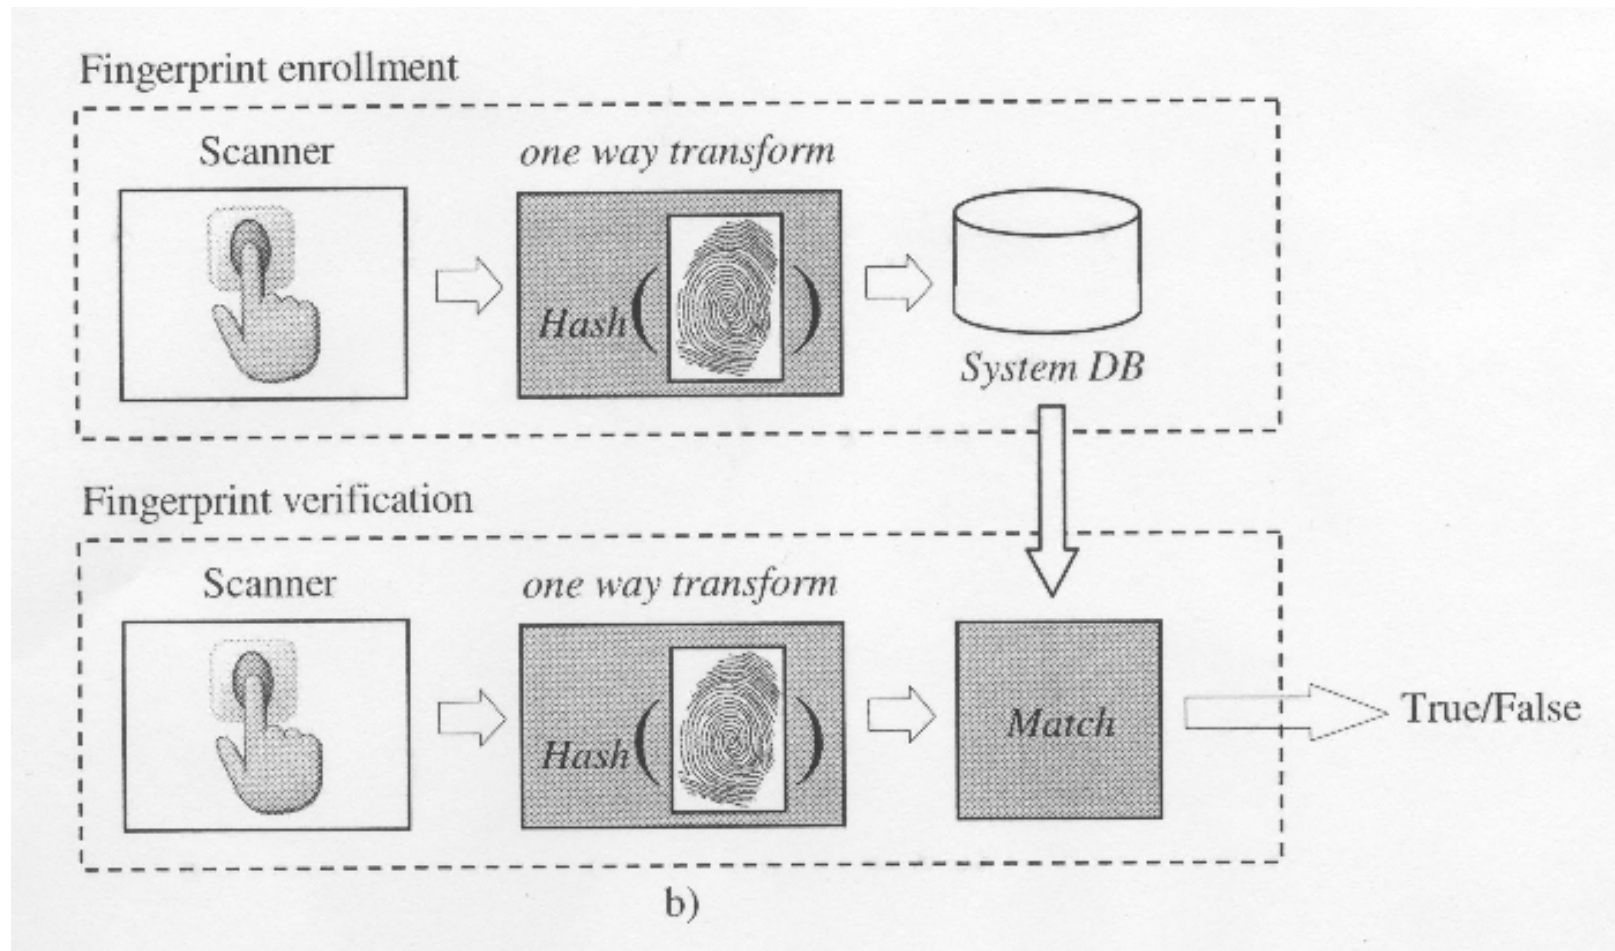

Research Directions:

- Liveness detection
- Biometric Encryption / Cancelable Biometrics

Challenges

- Biometric Variance
 - Samples from same user change with time
- Inconsistent Presentation
 - fingers placed differently, pressure applied
- Irreproducible Presentation
 - Glasses, moustache, cuts, bruises
- Imperfect Representation
 - Unordered, slight change in signal, sensors
- Biometric Matching
 - Score/probability based (0-1)

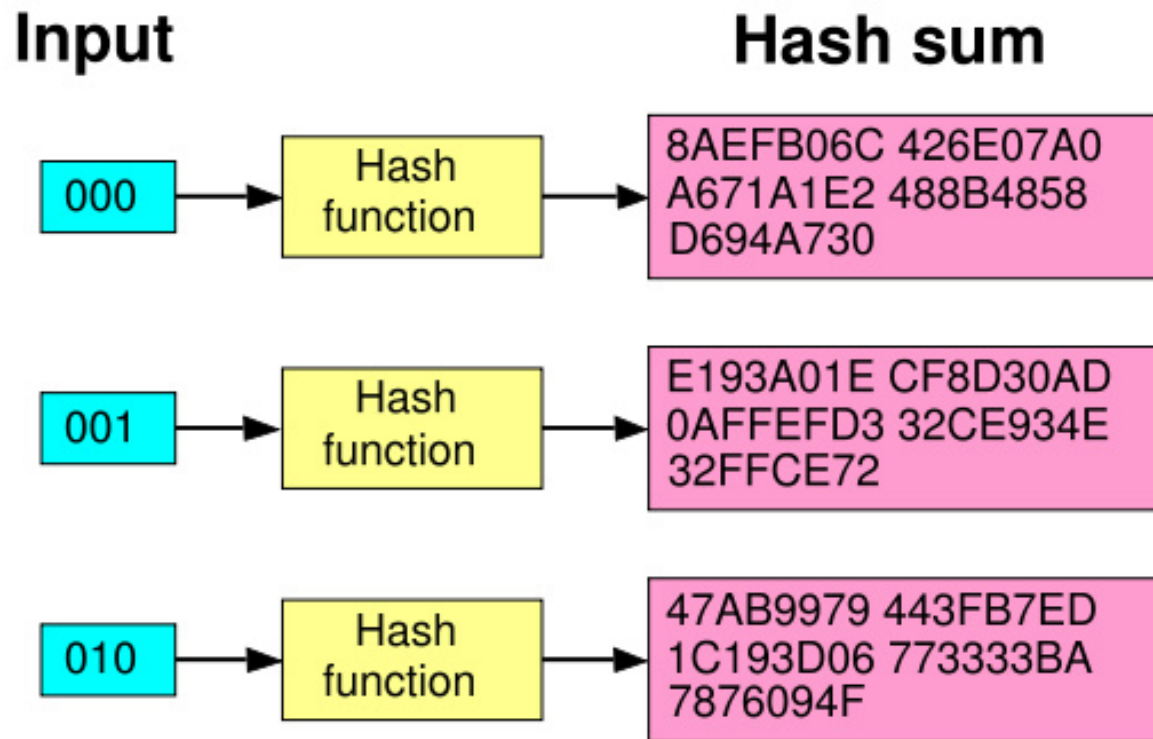

Securing Biometrics

Securing Biometrics

Comparison with plaintext

Avalanche Effect - input is changed slightly, the output changes significantly

Example

Rmpetltn

Can it be inverted to the secret ?

Rmpetltn

+

Drop chars at
2,5,7,9, 12,14

Can it be inverted to the secret ?

Noisy Situation

Properties

- Repeatabile

- Different instances of the biometric sample from the same user should produce the same key

- Security

- The key has to be non-invertible. The key should not leak information about the template or the user

Properties

- Discriminability
 - Samples from different individuals should produce different keys
- Cancelability
 - Keys could be cancelled
- Reusability
 - Keys can be reissued easily

Secure Biometrics*

- Security
 - Less susceptible to security attacks
 - Compliance with privacy laws
- Cancelability
 - revoked if compromised
 - reissued easily
- Anonymity
 - Removing true identity from the biometric
 - No retention of original biometric
- Multiplicity
 - Use of single biometric for multiple accounts
 - Cannot be cross-verified or identified

*SCAM Properties – Farooq *et al.*, 2007

Existing Methods

- Philosophy I
 - Generate stable representation of biometrics
 - Use conventional security algorithms
 - Perform matching in encrypted domain
- Philosophy II
 - Cannot generate reproducible representations
 - Devise non-invertible transforms
 - Perform matching in new domain

Existing Methods

- Biometric Encryption (I)
- Error-Correcting Codes (I)
- Fuzzy Schemes (I)
- Non-invertible Transforms (II)
- Others (I/II)

Existing Approaches

- Davida, Frankel, Matt (1998)
 - use error correcting codes, features should be ordered
- Biometric encryption (Soutar et al., 1998)
 - use filters for Fourier transform of fingerprint image
 - translation is accounted for, but not rotation

(example of such filters for face verification)

Figure 1. Block diagram showing the correlation process

Existing Approaches

- Ratha, Connell, Bolle [2001]
 - polynomial transform
 - need alignment

Figure 13 Example of noninvertible feature transform

Existing Approaches

- Fuzzy vault - Juels, Sudan [2002]
- Applications to fingerprints - Clancy et al.[2003]

Limitation:

Features should have similar values, does not account for global image transformations

Auxilliary Data

- Additional Data to facilitate alignment
 - Helper Data Systems Tuyls et al. '03, '04, '05
 - Orientation Field Flow Curves Uludag and Jain '06

Error-Correcting Codes

Error-correcting codes were designed to restore possibly corrupt data:

$$\underbrace{(a_1, \dots, a_k)}_{\text{data symbols}}, \underbrace{\dots, a_n}_{\text{check symbols}} \quad - (n,k)\text{-codes}$$

d - designed minimum distance of the code

Valid codes in n-dimensional code space

Error-Correcting Codes for Biometrics

Davida et al., 1998:

(a_1, \dots, a_k) - original biometric data

(a_{k+1}, \dots, a_n) - error correcting codes

$h(a_1, \dots, a_k)$ - some hash of original biometric data

Instead of original data, keep error-correcting code data and hash in the database

Matching:

$(a'_1, \dots, a'_k, a_{k+1}, \dots, a_n)$
- perform error correction and get (a''_1, \dots, a''_k)

Verify: $h(a_1, \dots, a_k) = h(a''_1, \dots, a''_k)$

Random Multispace Quantization

Teoh et al (2006)

- Use biometrics represented by a fixed feature vector (e.g. face projections by PCA, LDA, FDA)
- Project onto multiple random subspaces derived from external input (key)

$$b \rightarrow b' = R_k b$$

If dimension of projection space is less than the dimension of original space, the transformation is non-invertible

Variation:

For binary templates: discard some bits and make XOR with random vector

- Advantages
 - Actual biometric not stored
 - Auxiliary information increases inter-user variation
 - Error rates low* (if key is not stolen)
 - Easy to generate, revoke, reissue
- Disadvantages
 - Alignment of query and template an issue
 - Case when key is stolen
 - Multiplicity attacks still succeed

Biometric Hardening Monrose *et al* '99, '01, '01, '02

- Reminiscent to 'password salting'

The security improvements are questionable: lost key?

Transforms

- Non-invertible transforms of biometrics
- Key-based and keyless systems proposed

Transforms

- Advantages
 - Compatible with standard representations
 - Security, Cancelability, Anonymity, Multiplicity
- Disadvantages
 - Some methods require registration
 - Key-less systems usually have low accuracies

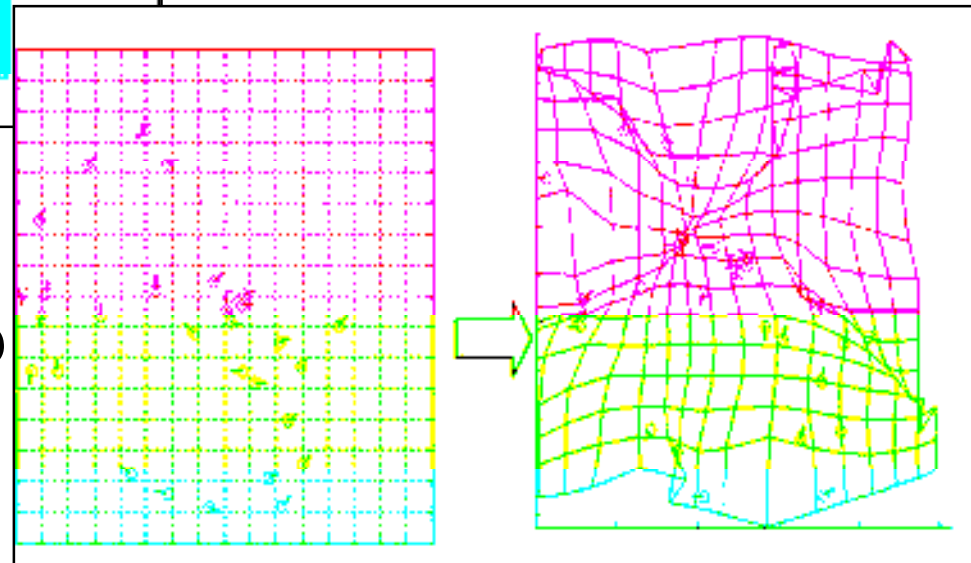

Surface Folding Ratha et al. '07

$$X' = x + K |\vec{G}(x, y)| + K \cos(\Phi_F(x, y))$$

$$Y' = y + K |\vec{G}(x, y)| + K \sin(\Phi_F(x, y))$$

$$\Theta' = \text{mod}(\theta + \Phi_G(x, y) + \Phi_{rand}, 2\pi)$$

Locally Smooth but not globally smooth

Surface Folding

- Advantages
 - Achieves cancelability, security and multiplicity
 - Compatible with standard minutiae based representations
 - Compatible with existing point-based matchers
- Disadvantages
 - Alignment of query and template is an issue
 - Assume stable points (core and delta) for alignment
 - Low Security

Symmetric Hashing Tulyakov et al 2007

Represent Minutia as complex numbers

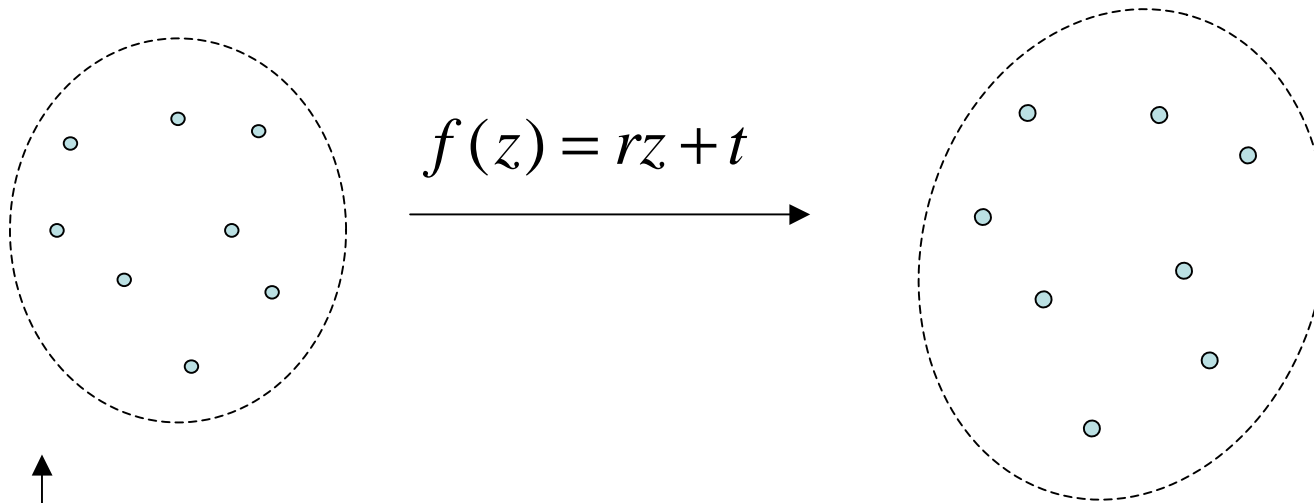

$$z = x + yi = \sqrt{x^2 + y^2} \left(\frac{x}{\sqrt{x^2 + y^2}} + \frac{y}{\sqrt{x^2 + y^2}} i \right)$$

Denote $|z| = \sqrt{x^2 + y^2}$ - magnitude of z

$$\text{Then } z = |z| \left(\frac{x}{|z|} + \frac{y}{|z|} i \right) = |z| (\cos \theta + i \sin \theta)$$

Transformation of minutiae set .

$$r = |r| (\cos \varphi + i \sin \varphi)$$

Multiplying by r means rotating by angle φ and scaling by factor $|r|$.

Hash functions of minutia points

Consider following functions of minutia positions:

$$h_1(c_1, c_2, \dots, c_n) = c_1 + c_2 + \dots + c_n$$

$$h_2(c_1, c_2, \dots, c_n) = c_1^2 + c_2^2 + \dots + c_n^2$$

⋮

$$h_m(c_1, c_2, \dots, c_n) = c_1^m + c_2^m + \dots + c_n^m$$

The values of these symmetric functions do not depend on the order of minutia points.

Hash of transformed minutiae

What happens with hash functions if minutia point set is transformed?

$$\begin{aligned}h_1(c'_1, c'_2, \dots, c'_n) &= c'_1 + c'_2 + \dots + c'_n \\ &= (rc_1 + t) + (rc_2 + t) + \dots + (rc_n + t) \\ &= r(c_1 + c_2 + \dots + c_n) + nt = rh_1(c_1, c_2, \dots, c_n) + nt\end{aligned}$$

$$\begin{aligned}h_2(c'_1, c'_2, \dots, c'_n) &= c'^2_1 + c'^2_2 + \dots + c'^2_n \\ &= (rc_1 + t)^2 + (rc_2 + t)^2 + \dots + (rc_n + t)^2 \\ &= r^2(c^2_1 + c^2_2 + \dots + c^2_n) + 2rt(c_1 + c_2 + \dots + c_n) + nt^2 \\ &= r^2h_2(c_1, c_2, \dots, c_n) + 2rth_1(c_1, c_2, \dots, c_n) + nt^2\end{aligned}$$

Finding transformation parameters

Thus $h_i(c'_1, c'_2, \dots, c'_n)$ can be expressed as a linear combinations of $h_j(c_1, c_2, \dots, c_n)$, $j \leq i$ with coefficients depending on transformation parameters r and t .

Denote:

$$h_i = h_i(c_1, c_2, \dots, c_n)$$
$$h'_i = h_i(c'_1, c'_2, \dots, c'_n)$$

Thus

$$h'_1 = rh_1 + nt$$
$$h'_2 = r^2h_2 + 2rth_1 + nt^2$$

And r, t can be calculated given h_1, h_2, h'_1, h'_2

Configurations

- n=2, m=1: for each minutia point we find its nearest neighbor, and

$$h_1(c_1, c_2) = \frac{c_1 + c_2}{2}$$

- n=3, m=1: for each minutia point we find two nearest neighbors and

$$h_1(c_1, c_2, c_3) = \frac{(c_1 + c_2 + c_3)}{3}$$

- n=3, m=2: for each minutia point find three nearest neighbors, and for each minutia triplet including original minutia point construct 2 hash functions

$$h_1(c_1, c_2, c_3) = \frac{(c_1 + c_2 + c_3)}{3}$$

$$h_2(c_1, c_2, c_3) = \frac{(c_1 - h_1)^2 + (c_2 - h_1)^2 + (c_3 - h_1)^2}{3}$$

Security

- If the number of stored hash functions h_i is less than the number of minutia points, it is not possible to find the positions of minutia points c_j from local hash values.
- Using system of hash equations is difficult, since it is not known which minutia correspond to particular hash value.

- Advantages

- No alignment of query and template required
- Achieves cancelability, security
- Compatible with standard minutiae based representations
- Compatible with existing point-based matchers

- Disadvantages

- Error Rates higher than many existing systems
- Security for existing configuration
- Multiplicity and reissuing
- Scoring

Linear Representations Farooq et al 2007

- Face representation in terms of Eigenfaces
- Iris representation as bit strings
- Can we devise a linear representation for fingerprints?
 - new way to construct anonymous fingerprint representations
 - representation invariant to transformation (translation/rotation)

Motivation

- Minutiae triplets form triangles
- Fingerprint can be linearly represented as a set of triangles
- The triangle geometry does not change under rigid transformation
- Multiple invariants can be associated with triangles

Invariant features

- **Independent triangle features**
 - The sides
- **Dependent triangle feature**
 - Height at largest side
- **Fingerprint features**
 - Minutiae angles with respect to triangle

Triangles can be enumerated

<i>F</i>

- Advantages
 - No alignment of query and template required
 - Achieves cancelability, security
 - Compatible with standard minutiae based representations
 - Low Error Rates reported on very large sets
 - Multiplicity and reissuing very easy
- Disadvantages
 - Security for existing configuration ??

Conclusion

- Open area of research
- Increasingly gaining importance
- Process Biometric and use conventional (time tested) security techniques ?
- Secure Biometric using new techniques ?
