NONMETRIC METHODS
Recognition with Strings

Pattern Recognition

CSE 555/655
Attribute Lists

• Nominal Data
  – No natural notion of similarity or ordering
  – E.g., a fruit = (red, shiny, sweet, small)

• Distance between vectors cannot be measured
  – Nearest-neighbor uses distance
  – Neural network uses similarity of outputs
Strings

- Patterns are ordered sequences, or variable length strings of discrete items
- Examples
  - Sequence of letters in an English word
  - In DNA, bases in a gene sequence
  - In JOCR, brush strokes recognized by neural network, then string matching for OCR
- Move away from pdfs and metrics to syntactic methods
Gene Sequence

- DNA bases in gene sequence
- E.g., AGCTTTCGAATC
- Letters stand for nucleic acids
  - A: adenine
  - G: guanine
  - C: cytosine
  - T: thymine
String Pattern Classification

• String elements are nominal
  – Characters, letters, or symbols
• No obvious notion of distance between strings
• Strings need not be of same length
• Strings are not vectors, yet we will use notation, \( x = \text{AGCTTC} \)
String Terminology

- Patterns, Strings, templates, words
- A long string is denoted *text*
- Any continuous string that is part of \( x \) is a substring, segment, or *factor* of \( x \)
  - E.g., “GCT” is a factor of “AGCTTC”
String Recognition Problems

• Many computational problems with strings
• Problems of greatest importance:
  1. **String Matching**: Given x and text, determine whether x is a factor of text and if so, where it appears
  2. **Edit Distance**: Given two strings x and y compute minimum number of basic operations—insertions, deletions and substitutions—to transform x to y
3. **String Matching with errors:** Given $x$ and $text$, find the locations in $text$ where the cost or distance to any factor of $x$ is minimal.
String Problems

4. String Matching with “Don’t-care symbol”: Same as basic string matching, but with special symbol-- * which can match any other symbol., e.g.,

Given DNA segment $x =$

AGCCG*****GACTG

Motifs:
Important for coding protein

Inert: no function

Is *text* in the class of sequences that could yield the particular protein
