Topics

• Linear Gaussian Model
• Learning Parameters of a Gaussian Bayesian Network
• Multivariate Gaussian representations
  1. Covariance Form
  2. Information Form:
     1. Bayesian Networks
     2. Markov Random Fields
Linear Gaussian Model

- \( Y \) has a linear Gaussian model with continuous parents \( X_1, \ldots, X_k \) with parameters \( \beta_0, \ldots, \beta_k \) and \( \sigma^2 \) such that

\[
P(Y|X_1, \ldots, X_k) \sim N(\beta_0 + \beta_1 X_1 + \ldots + \beta_k X_k; \sigma^2)
\]

- In vector notation

\[
P(Y|X) \sim N(\beta_0 + \beta^T X; \sigma^2)
\]

- Can be viewed as \( Y = \beta_0 + \beta_1 X_1 + \ldots + \beta_k X_k + \varepsilon \)

  - i.e., \( Y \) is a linear function of the variables with the addition of Gaussian noise with mean \( 0 \) and variance \( \sigma^2 \)
Gaussian Bayesian Network

- **Definition:** All variables are Gaussian and all CPDs are linear Gaussian
- Let $Y$ be a linear Gaussian of its parents $X_1, \ldots, X_k$
  - i.e., mean of $Y$ is a linear combination of means of Gaussian parents
  \[
  P(Y|X) \sim N(\beta_0 + \beta^t X; \sigma^2) \]
- If $X_1, \ldots, X_k$ are jointly normal $N(\mu; \Sigma)$ then the distribution of $Y$ is normal $N(\mu_Y; \sigma^2_Y)$ where
  \[
  \mu_Y = \beta_0 + \beta^t \mu \quad \text{and} \quad \sigma^2_Y = \sigma^2 + \beta^t \Sigma \beta
  \]
  The joint distribution over $(X,Y)$ is normal with
  \[
  \text{Cov}[X_i : Y] = \sum_{j=1}^{k} \beta_j \Sigma_{i,j}
  \]
Learning parameters of Gaussian Bayesian Network

- All variables are Gaussian
  \[ P(X|u_1,..u_k) \sim N(\beta_0 + \beta_1 u_1 +.. \beta_k u_k; \sigma^2) \]
- Task is to learn the parameters
  \[ \theta_{X|U} = \{\beta_0, \beta_1,.. \beta_k, \sigma^2\} \]
- To find ML estimate of parameters, define log-likelihood
  \[
  \log L_x(\theta_{X|U} : D) = \sum_m \left[ -\frac{1}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \left( \beta_0 + \beta_1 u_1[m] + .. \beta_k u_k[m] - x[m] \right)^2 \right]
  \]
- Closed-form solutions for parameters
Solving for the parameters

• Gradient of log-likelihood wrt $\beta_0$
  \[-\frac{1}{\sigma^2} \left( M\beta_0 + \beta_1 \sum_m u_1[m] + ... + \beta_k \sum_m u_k[m] - x[m] \right)\]

• Equating to zero and rearranging we get
  \[\frac{1}{M} \sum_m x[m] = \beta_0 + \beta_1 \frac{1}{M} \sum_m u_1[m] + ... + \beta_k \frac{1}{M} \sum_m u_k[m]\]

• All the summations can be obtained from data thus giving us a linear equation

• Similarly we get $k$ more linear equations by taking derivatives wrt $\beta_i$

• Standard linear algebra techniques are used to solve $k + 1$ simultaneous equations
Solving Linear Equations

1. Matrix Solution: \( Ax = b \)
Therefore \( x = A^{-1}b \)

\[
\begin{align*}
\begin{bmatrix}
  a_{11} & a_{12} & \cdots & a_{1n} \\
  a_{21} & a_{22} & \cdots & a_{2n} \\
  \vdots & \vdots & \ddots & \vdots \\
  a_{m1} & a_{m2} & \cdots & a_{mn}
\end{bmatrix}
\begin{bmatrix}
  x_1 \\
  x_2 \\
  \vdots \\
  x_n
\end{bmatrix}
&=
\begin{bmatrix}
  b_1 \\
  b_2 \\
  \vdots \\
  b_m
\end{bmatrix}
\]

2. Gaussian Elimination

\[
\begin{aligned}
x + 3y - 2z &= 5 \\
3x + 5y + 6z &= 7 \\
2x + 4y + 3z &= 8
\end{aligned}
\]
Estimating variance

• Taking derivative of likelihood and setting to zero, we get

\[ \sigma^2 = \text{Cov}_D[X;X] - \sum_i \sum_j \beta_i \beta_j \text{Cov}_D[U_i;U_j] \]

– where

\[ \text{Cov}_D[X;Y] = E_D[X \cdot Y] - E_D[X] \cdot E_D[Y] \]

\[ E_D[X \cdot Y] = \frac{1}{M} \sum_m x[m]y[m] \quad E_D[X] = \frac{1}{M} \sum_m x[m] \]

• First term is the empirical variance of \( X \)

• Other terms are empirical covariances of inputs
Properties of Linear Gaussian

- **Advantage**: Simple model that captures many dependencies
- **Disadvantage**: cannot capture dependence of variance of child on values of parents
  - Can be extended
    - E.g., mean of $Y$ is $\sin(x_1)x^2$
    - Variance is $(x_3/x_4)^2$
- But linear Gaussian is a good approximation
- Provides an alternative for representing multivariate Gaussian distributions
Multivariate Gaussian

• Three equivalent representations

1. Basic parameterization (covariance form)

\[ p(x) = \frac{1}{(2\pi)^{d/2} |\Sigma|^{1/2}} \exp \left[ -(x - \mu)' \Sigma^{-1} (x - \mu) \right] \]

\[
\mu = \begin{bmatrix} 1 & -3 & 4 \\ -3 & 5 & 2 \\ 4 & 2 & -2 \end{bmatrix} \\
\Sigma = \begin{bmatrix} 4 & 2 & -2 \\ 2 & 5 & -5 \\ -2 & -5 & 8 \end{bmatrix}
\]

\[ \mu = E[x] \]
\[ \Sigma = E[xx'] - E[x]E[x]' \]

\[ x_1 \text{ is negatively correlated with } x_3 \]
\[ x_2 \text{ is negatively correlated with } x_3 \]

2. Gaussian Bayesian network (information form)

• Conversion to Information form (precision matrix) captures conditional independencies

3. Gaussian Markov Random Field

• Easiest conversion
Gaussian Distribution Operations

- There are two main operations we wish to perform on a distribution:
  1. Marginal distribution over some subset $Y$
  2. Conditioning the distribution on some $Z=z$
- Marginalization is trivially performed in the covariance form
- Conditioning a Gaussian is very easy to perform in the information form
Marginalization in Covariance Form

• Can be simply read from the mean and covariance matrix
• Decompose the mean and covariance as:

\[
p(X, Y) = N\left(\begin{pmatrix} \mu_X \\ \mu_Y \end{pmatrix}; \begin{bmatrix} \Sigma_{xx} & \Sigma_{xy} \\ \Sigma_{yx} & \Sigma_{yy} \end{bmatrix}\right)
\]

• Marginal distribution over \( Y \) is a normal distribution \( N(\mu_Y; \Sigma_{yy}) \)
Determining Conditional Distribution using Covariance Form

- Let \((X,Y)\) have a normal distribution defined by

\[
p(X,Y) = N\left( \begin{pmatrix} \mu_X \\ \mu_Y \end{pmatrix}; \begin{bmatrix} \Sigma_{XX} & \Sigma_{XY} \\ \Sigma_{YX} & \Sigma_{YY} \end{bmatrix} \right)
\]

- Then marginal distribution \(P(Y|X)\) is given by

\[
P(Y|X) \sim N(\beta_0 + \beta^T X; \sigma^2)
\]

where

\[
\begin{align*}
\beta_0 &= \mu_Y - \Sigma_{YX} \Sigma_{XX}^{-1} \mu_X \\
\beta &= \Sigma_{XX}^{-1} \Sigma_{YX} \\
\sigma^2 &= \Sigma_{YY} - \Sigma_{YX} \Sigma_{XX}^{-1} \Sigma_{XY}
\end{align*}
\]

- This allows us to take a joint Gaussian distribution and construct a Bayesian network
Constructing a BN from a Gaussian

• **Definition of I-map**
  - $I$ is set of independence assertions of form $(X \perp Y/ Z)$, which are true of distribution $P$
  - $G$ is an I-map of $P$ implies: $I_G \subseteq I$
    - Minimal I-map: removal of a single edge renders the graph not an I-map

• **Algorithm uses the principle that for $Z$ to be parents of node $X$, $(X \perp Y/ Z)$ where $Y = \chi-Z$**
  - need to check if $P(X|Z)$ is independent of $P(Y_i|Z)$
    - Can be done using deviance measure: $\chi^2$ or mutual info (KL-div)
      \[
      d_x(D) = \sum_{x_i} \frac{(M[x_i] - M \cdot \hat{P}(x_i) \cdot \hat{P}(x_i))^2}{M \cdot \hat{P}(x_i) \cdot \hat{P}(x_i)}
      \]
      \[
      d_y(D) = \frac{1}{M} \sum_{x_i,x_j} M[x_i,x_j] \log \frac{M[x_i,x_j]}{M[x_i]M[x_j]}
      \]
    - Simpler Method: use Information form of Gaussian
BN from conditional independencies

Algorithm computes an I-Map which may not be unique

- \( \mathcal{X} = \{ X_1, \ldots, X_n \} \): set of random variables
- \( I \): set of independencies

```latex
1 \quad \text{Set } G \text{ to an empty graph over } \mathcal{X}
2 \quad \text{for } i = 1, \ldots, n
3 \quad \quad U \leftarrow \{X_1, \ldots, X_{i-1}\} \quad // U \text{ is the current candidate for parents of } X_i
4 \quad \quad \text{for } U' \subseteq \{X_1, \ldots, X_{i-1}\}
5 \quad \quad \quad \text{if } U' \subseteq U \text{ and } (X_i \independent \{X_1, \ldots, X_{i-1}\} - U' \mid U') \in I \text{ then}
6 \quad \quad \quad \quad U \leftarrow U'
7 \quad \quad \quad \quad \text{At this stage } U \text{ is a minimal set satisfying } (X_i \independent \{X_1, \ldots, X_{i-1}\} - U \mid U)
8 \quad \quad \quad \quad \text{Now set } U \text{ to be the parents of } X_i
9 \quad \quad \text{for } X_j \in U
10 \quad \quad \quad \text{Add } X_j \rightarrow X_i \text{ to } G
11 \quad \text{return } G
```
Information form gives edges of BN

- **Standard Form**
  \[
p(x) = \frac{1}{(2\pi)^{d/2}|\Sigma|^{1/2}} \exp\left[ -\frac{1}{2}(x-\mu)'\Sigma^{-1}(x-\mu) \right]
\]

- **Using Precision**
  \[
  J = \Sigma^{-1}
  \]
  \[
  -\frac{1}{2}(x-\mu)'\Sigma^{-1}(x-\mu) = -\frac{1}{2}(x-\mu)' J (x-\mu)
  = -\frac{1}{2} [x'Jx - 2x'J\mu + \mu'J\mu]
  \]
  
  - Since last term is constant, we get information form

  \[
p(x) \propto \exp\left( -\frac{1}{2} x'Jx + (J\mu)'x \right)
  \]

  - \(J\mu\) is called the potential vector

- \(J_{i,j} = 0\) iff \(X_i\) is independent of \(X_j\) given \(\chi - \{X_i, X_j\}\)

  - **Example**

  \[
  \begin{bmatrix}
  1 & -3 & 4 \\
  -3 & 2 & 5 \\
  4 & 5 & -2
  \end{bmatrix}
  \]

  \[
  \begin{bmatrix}
  0.3125 & -0.125 & 0 \\
  -0.125 & 0.5833 & 0.3333 \\
  0 & 0.3333 & 0.3333
  \end{bmatrix}
  \]

  - Since \(J_{1,3} = 0\), \(x_1\) and \(x_3\) are independent given \(x_2\)

  - Non-zero entries define edges (non-correlations)
Gaussian Markov Random Fields

• Follows directly from information form

\[ p(x) \propto \exp \left( -\frac{1}{2} x' J x + (J \mu)' x \right) \]

– which is obtained from covariance form with \( J = \Sigma^{-1} \)

\[ p(x) = \frac{1}{(2\pi)^{d/2} |\Sigma|^{1/2}} \exp \left[ (x - \mu)' \Sigma^{-1} (x - \mu) \right] \]

• Break-up exponent into two types of terms

– Using the potential vector \( h = J \mu \)

– Terms involving single variable \( X_i \)

\[ -\frac{1}{2} J_{i,i} x_i^2 + h_i x_i \]

• Called node potentials

Terms involving pairs of variables \( X_i, X_j \)

\[ -\frac{1}{2} \left[ J_{i,j} x_i x_j + J_{j,i} x_j x_i \right] = -J_{i,j} x_i x_j \]

• Called edge potentials (when \( J_{i,j} = 0 \), there is no edge)
