Structure Learning in Bayesian Networks

Sargur Srihari
srihari@cedar.buffalo.edu
Topics

• Problem Definition
• Overview of Methods
• Constraint-Based Approaches
• Independence Tests
• Testing for Independence
• Structure Scores
Problem Assumptions

• We do not know the structure
• Data set is fully observed
  – A strong assumption
• Partially observed data are dealt with using other methods
  – Gradient Ascent and EM
• Assume data $\mathcal{D}$ is generated i.i.d. from distribution $\mathcal{P}^*(X)$
• Assume that $P^*$ is induced by BN $G^*$
Need for BN Structure Learning

• **Structure**
  - Causality cannot easily be determined by experts
  - Variables and Structure may change with new data sets

• **Parameters**
  - When structure is specified by an expert
    • Experts cannot usually specify parameters
  - Data sets can change over time
  - Need to learn parameters when structure is learnt
To what extent do independencies in $G^*$ manifest in $D$?

- Two coins X and Y tossed independently
- We are given data set of 100 instances
- Learn a model for this scenario
- Typical data set:
  - 27 head/head
  - 22 head/tail
  - 25 tail/head
  - 26 tail/tail
- Are the coins independent?
Coin Tossing Probabilities

• Marginal Probabilities
  \[ P(X=\text{head}) = 0.49, \ P(X=\text{tail}) = 0.51, \ P(Y=\text{head}) = 0.48, \ P(Y=\text{tail}) = 0.52 \]

• Products of marginals:
  - \[ P(X=\text{head}) \times P(Y=\text{head}) = 0.49 \times 0.49 = 0.24 \]
  - \[ P(X=\text{head}) \times P(Y=\text{tail}) = 0.49 \times 0.51 = 0.25 \]
  - \[ P(X=\text{tail}) \times P(Y=\text{head}) = 0.51 \times 0.48 = 0.245 \]
  - \[ P(X=\text{tail}) \times P(Y=\text{tail}) = 0.51 \times 0.52 = 0.26 \]

• Joint Probabilities
  - \[ P(XY=\text{head-head}) = 0.27 \]
  - \[ P(XY=\text{head-tail}) = 0.22 \]
  - \[ P(XY=\text{tail-head}) = 0.25 \]
  - \[ P(XY=\text{tail-tail}) = 0.26 \]

• According to empirical distribution: not independent

• But we suspect independence
  - since probability of getting exactly 25 in each category is small (approx. 1 in 1,000)
Rain-Soccer Probabilities

- Scan sports pages for 100 days
- Select an article at random to see
  - If there is mention of rain and soccer

Marginal Probabilities

\[ P(X=\text{rain}) = 0.49, \quad P(X=\text{no rain}) = 0.51, \quad P(Y=\text{soccer}) = 0.48, \quad P(Y=\text{no soccer}) = 0.52 \]

Joint Probabilities

- \[ P(XY=\text{rain-soccer}) = 0.27 \]
- \[ P(XY=\text{rain-no soccer}) = 0.22 \]
- \[ P(XY=\text{no rain-soccer}) = 0.25 \]
- \[ P(XY=\text{no rain-no soccer}) = 0.26 \]

- We suspect there is a weak connection (not independent)
- It is hard to be sure whether the true underlying model has an edge between X and Y
Goal of Learning

• Correctly constructing network depends on learning goal

• Goal 1: Knowledge Discovery
  – By examining dependencies in the learned network we can learn dependency of variables
    • Can also be done using statistical independence tests
  – Bayesian network reveals much finer structure
    • Distinguish between direct and indirect independencies both of which lead to correlations
Caution in Knowledge Discovery Goal

• If goal is to understand domain structure best answer we can get is to recover $G^*$
• Since there are many I-maps for P* we cannot distinguish them from $\mathcal{D}$
• Thus $G^*$ is not identifiable
• Best we can do is recover $G^*$'s equivalence class
Too few or too many edges in $G^*$

- Even learning equivalence class of networks is hard
- Data sampled is noisy
- Need to make decisions about including edges we are less sure about
  - Too few edges means missing out on dependencies
  - Too many edges means spurious dependencies
Goal of Density Estimation

• Goal is to reason about instances not in our training data
• Network to generalize to new instances
• We want true $G^*$ which captures true dependencies and independencies
• If we make mistakes, better to include too many edges rather than too few edges
  – With an overly complex structure we can still capture $P^*$
• But this also fallacious
Data Fragmentation with too many edges

- Data set with 20 tosses:
  - 3 head/head
  - 6 head/tail
  - 5 tail/head
  - 6 tail/tail

- Marginal Probability
  \[ P(Y=\text{head}) = \frac{3+5}{20} = .4 \quad \text{Based on 20 instances} \]

- Introduce spurious correlation between X and Y

- Conditional Probabilities
  \[ P(Y=\text{head} \mid X=\text{head}) = \frac{3}{9} = \frac{1}{3} \quad \text{Based on 9 instances} \]
  \[ P(Y=\text{head} \mid X=\text{tail}) = \frac{5}{11} \]

If there was independence \( P(Y/X)=P(Y) \)

Data fragmentation causes anomaly

Std dev with \( M \) samples is \( \frac{1}{\sqrt{M}} \) which is .11 for 20 and .17 for 9
Data Fragmentation with spurious edges

- In a table CPD no of bins grows exponentially with no of parents
- Cost of adding a parent can be very large
- Cost of adding a parent grows with no of parents already there
- It is better to obtain a sparser structure
- We can sometimes learn a better model by learning a model with fewer edges even if it does not represent the true distribution
Overview of methods

• Three approaches to learning structure

1. Constraint-based
   – Test for conditional dependence and independence in the data
   – Sensitive to failures in independence tests

2. Score-based
   – BN specifies a statistical model
   – Problem is to select best structure
   – Hypothesis space is super-exponential \( 2^{O(n^2)} \)

3. Bayesian model averaging
   – Generate ensemble of possible structures
BN Structure Learning Algorithms

- **Constraint-based**
  - Find structure that best explains determined dependencies
    - Sensitive to errors in testing individual dependencies
      - Koller and Friedman, 2009

- **Score-based**
  - Search the space of networks to find high-scoring structure
  - Since space is super-exponential, need heuristics
    - K2 algorithm (Cooper & Herskovits, 1992)
    - Optimized Branch and Bound (deCampos, Zheng and Ji, 2009)

- **Bayesian Model Averaging**
  - Prediction over all structures
  - May not have closed form, Limitation of $X^2$
    - Peters, Danzing and Scholkopf, 2011
Elements of BN Structure Learning

1. Local: Independence Tests
   1. Measures of Deviance-from-independence between variables
   2. Rule for accepting/rejecting hypothesis of independence

2. Global: Structure Scoring
   – Goodness of Network
Independence Tests

1. For variables $x_i, x_j$ in data set $\mathcal{D}$ of $M$ samples
   1. Pearson’s Chi-squared ($X^2$) statistic
      $$d_{X^2}(\mathcal{D}) = \sum_{x_i, x_j} \frac{(M[x_i, x_j] - M \cdot \hat{P}(x_i) \cdot \hat{P}(x_j))^2}{M \cdot \hat{P}(x_i) \cdot \hat{P}(x_j)}$$
      Sum over all values of $x_i$ and $x_j$
      - Independence $\Rightarrow d_X(\mathcal{D}) = 0$, larger value when Joint $M[x,y]$ and expected counts (under independence assumption) differ

2. Mutual Information (K-L divergence) between joint and product of marginals
   $$d_I(\mathcal{D}) = \frac{1}{M} \sum_{x_i, x_j} M[x_i, x_j] \log \frac{M[x_i, x_j]}{M[x_i]M[x_j]}$$
   - Independence $\Rightarrow d_I(\mathcal{D}) = 0$, otherwise a positive value

• 2. Decision rule

$$R_d(\mathcal{D}) = \begin{cases} 
\text{Accept } d(\mathcal{D}) \leq t & \text{False Rejection probability due to choice of } t \text{ is its p-value} \\
\text{Reject } d(\mathcal{D}) > t & 
\end{cases}$$
Structure Scoring

1. Log-likelihood Score for $G$ with $n$ variables

$$score_L(G : D) = \sum_{D} \sum_{i=1}^{n} \log \hat{P}(x_i | pax_i)$$

Sum over all data and variables $x_i$

2. Bayesian Score

$$score_B(G : D) = \log p(D | G) + \log p(G)$$

3. Bayes Information Criterion

– With Dirichlet prior over graphs

$$score_{BIC}(G : D) = l(\hat{\theta}_G : D) - \frac{\log M}{2} Dim(G)$$
Consider pairs of variables ordered by $\chi^2$ value.
Add next edge if score is increased.

$G^* = \{V, E^*, \theta^*\}$
Start
Score $s_{k-1}$

$G_{c1} = \{V, E_{c1}, \theta_{c1}\}$
Candidate $x_4 \rightarrow x_5$
Score $s_{c1}$

Choose $G_{c1}$ or $G_{c2}$ depending on which one increases the score $s(D, G)$
evaluate using cross validation on validation set
