Mixture of Gaussians

Sargur Srihari
srihari@cedar.buffalo.edu
Mixtures of Gaussians

• Also Called as Finite Mixture Models (FMMs)

\[ p(x) = \sum_{k=1}^{K} \pi_k N(x \mid \mu_k, \Sigma_k) \]

Goal:
Determine the three sets of parameters \( \pi, \mu, \Sigma \) using maximum likelihood
Gaussian Mixture Model

- A linear superposition of Gaussian components
- Provides a richer class of density models than the single Gaussian
- GMM are formulated in terms of discrete latent variables
  - Provides deeper insight
  - Motivates EM algorithm
    - Which gives a maximum likelihood solution to no. of components and their means/covariances

**GMM Formulation**

- **Linear superposition of** $K$ **Gaussians:**
  \[
  p(x) = \sum_{k=1}^{K} \pi_k N(x | \mu_k, \Sigma_k)
  \]

- **Introduce a latent variable** $z$ **that has** $K$ **values**
  - Use 1-of-$K$ representation
    - Let $z = z_1, \ldots, z_K$ whose elements are $z_k \in \{0, 1\}$ and $\sum z_k = 1$
    - There are $K$ possible states of $z$ corresponding to $K$ components

- **Define joint distribution** $p(x, z) = p(x | z) p(z)$
  - $x$ is observed variable
  - $z$ is hidden or missing variable
Specifying $p(z), z = \{z_1, \ldots, z_K\}$

- Associate a probability with each component $z_k$
  - Denote $p(z_k = 1) = \pi_k$ where parameters satisfy $0 \leq \pi_k \leq 1$ and $\sum_{k=1}^{K} \pi_k = 1$

- Because $z$ uses 1-of-$K$ it follows that
  
  $$p(z) = \prod_{k=1}^{K} \pi_k^{z_k}$$

  With one component $p(z_1) = \pi_1^{z_1}$
  
  With two components $p(z_1, z_2) = \pi_1^{z_1} \pi_2^{z_2}$

  - since components are mutually exclusive and hence are independent
Conditional distribution $p(x|z)$

- For a particular component (value of $z$)
  \[ p(x \mid z_k = 1) = N(x \mid \mu_k, \Sigma_k) \]

- Thus $p(x|z)$ can be written in the form
  \[ p(x \mid z) = \prod_{k=1}^{K} N(x \mid \mu_k, \Sigma_k)^{z_k} \quad \text{Due to the exponent $z_k$ all product terms except for one equal one} \]

- Thus marginal distribution of $x$ is obtained by summing over all possible states of $z$
  \[ p(x) = \sum_z p(z)p(x \mid z) = \sum_z \prod_{k=1}^{K} \pi_k^{z_k} N(x \mid \mu_k, \Sigma_k)^{z_k} = \sum_{k=1}^{K} \pi_k N(x \mid \mu_k, \Sigma_k) \]

- This is the standard form of a Gaussian mixture
Latent Variable

• If we have observations $x_1, \ldots, x_N$
• Because marginal distribution is in the form
  
  $$p(x) = \sum_z p(x, z)$$

  – It follows that for every observed data point $x_n$ there is a corresponding latent vector $z_n$, i.e., its sub-class

• Thus we have found a formulation of Gaussian mixture involving an explicit latent variable
  – We are now able to work with joint distribution $p(x, z)$ instead of marginal $p(x)$

• Leads to significant simplification through introduction of expectation maximization
Another conditional probability (Responsibility)

- In EM $p(z \mid x)$ plays a role
- The probability $p(z_k=1 \mid x)$ is denoted $\gamma(z_k)$
- From Bayes theorem

$$
\gamma(z_k) \equiv p(z_k = 1 \mid x) = \frac{p(z_k = 1) p(x \mid z_k = 1)}{\sum_{j=1}^{K} p(z_j = 1) p(x \mid z_j = 1)} = \frac{\pi_k N(x \mid \mu_k, \Sigma_k)}{\sum_{j=1}^{K} \pi_j N(x \mid \mu_j, \Sigma_j)}
$$

- View $p(z_k = 1) = \pi_k$ as prior probability of component $k$
- $\gamma(z_k) = p(z_k = 1 \mid x)$ as the posterior probability
- It is also the responsibility that component $k$ takes for explaining the observation $x$
Plan of Discussion

• Next we look at
  1. How to get data from a mixture model synthetically and then
  2. How to estimate the parameters from the data
Synthesizing data from mixture

- Use ancestral sampling
  - Start with lowest numbered node and draw a sample,
    - Generate sample of \( z \), called \( z^\wedge \)
    - Move to successor node and draw a sample given the parent value, etc.
  - Then generate a value for \( x \) from conditional \( p(x|z^\wedge) \)

Samples from \( p(x,z) \) are plotted according to value of \( x \) and colored with value of \( z \)

- Samples from marginal \( p(x) \) obtained by ignoring values of \( z \)
Illustration of responsibilities

• Evaluate for every data point
  – Posterior probability of each component
• Responsibility $\gamma(z_{nk})$ is associated with data point $x_n$
• Color using proportion of red, blue and green ink
  – If for a data point $\gamma(z_{n1}) = 1$ it is colored red
  – If for another point $\gamma(z_{n2}) = \gamma(z_{n3}) = 0.5$ it has equal blue and green and will appear as cyan
Maximum Likelihood for GMM

- We wish to model data set \{x_1, \ldots, x_N\} using a mixture of Gaussians (\(N\) items each of dimension \(D\)).
- Represent by \(N \times D\) matrix \(X\), where the \(N^{th}\) row is given by \(x_n^T\).
- Represent \(N\) latent variables with \(N \times K\) matrix \(Z\) with rows \(z_n^T\).
- Bayesian Network for \(p(x,Z)\) is 

We are given \(N\) i.i.d. samples \(\{x_n\}\) with unknown latent points \(\{z_n\}\) with parameters \(\pi_n\).

The samples have parameters: mean \(\mu\) and covariance \(\Sigma\).

Goal is to estimate the three sets of parameters.
Likelihood Function for GMM

Mixture density function is

\[ p(x) = \sum_z p(z) p(x \mid z) = \sum_{k=1}^{K} \pi_k N(x \mid \mu_k, \Sigma_k) \]

Therefore Likelihood function is

\[ p(X \mid \pi, \mu, \Sigma) = \prod_{n=1}^{N} \left\{ \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\} \]

Therefore log-likelihood function is

\[ \ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\} \]

Which we wish to maximize

A more difficult problem than for a single Gaussian
Maximization of Log-Likelihood

\[
\ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\}
\]

• Goal is to estimate the three sets of parameters \( \pi, \mu, \Sigma \)

• Before proceeding with the m.l.e. briefly mention two technical issues:
  – Problem of singularities
  – Identifiability of mixtures
Problem of Singularities with Gaussian mixtures

• Consider Gaussian mixture
  – components with covariance matrices $\Sigma_k = \sigma_k^2 I$

• Data point that falls on a mean $\mu_j = x_n$ will contribute to the likelihood function

$$N(x_n \mid x_n, \sigma_j^2 I) = \frac{1}{(2\pi)^{1/2}} \frac{1}{\sigma_j}$$

since $\exp(x_n - \mu_j)^2 = 1$

• As $\sigma_j \to 0$ term goes to infinity

• Therefore maximization of log-likelihood

$$\ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^N \ln \left\{ \sum_{k=1}^K \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\}$$

  – Does not happen with a single Gaussian
    • Multiplicative factors go to zero
    – Does not happen in the Bayesian approach

• Problem is avoided using heuristics
  – Resetting mean or covariance
Problem of Identifiability

A density \( p(x \mid \theta) \) is identifiable if \( \theta \neq \theta' \) then there is an \( x \) for which \( p(x \mid \theta) \neq p(x \mid \theta') \)

A \( K \)-component mixture will have a total of \( K! \) equivalent solutions

- Corresponding to \( K! \) ways of assigning \( K \) sets of parameters to \( K \) components
  - E.g., for \( K=3 \) \( K!=6 \): 123, 132, 213, 231, 312, 321
- For any given point in the space of parameter values there will be a further \( K!-1 \) additional points all giving exactly same distribution

- However any of the equivalent solutions is as good as the other

Two ways of labeling three Gaussian subclasses
EM for Gaussian Mixtures

• EM is a method for finding maximum likelihood solutions for models with latent variables

• Begin with log-likelihood function

\[
\ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\}
\]

• We wish to find \( \pi, \mu, \Sigma \) that maximize this quantity

• Take derivatives in turn w.r.t
  – Means \( \mu_k \) and set to zero
  – covariance matrices \( \Sigma_k \) and set to zero
  – mixing coefficients \( \pi_k \) and set to zero
EM for GMM: Derivative wrt $\mu_k$

- Begin with log-likelihood function

$$\ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\}$$

- Take derivative w.r.t the means $\mu_k$ and set to zero
  - Making use of exponential form of Gaussian
  - Use formulas:
    - $\frac{d}{dx} \ln u = \frac{u'}{u}$ and $\frac{d}{dx} e^u = e^u u'$
    - We get
      $$0 = \sum_{n=1}^{N} \frac{\pi_k N(x_n \mid \mu_k, \Sigma_k)}{\sum_j \pi_j N(x_n \mid \mu_j, \Sigma_j)} \sum_k^{-1} (x_n - \mu_k)$$

$\gamma(z_{nk})$ the posterior probabilities
M.L.E. solution for Means

- Multiplying by $\sum_k (assuming non-singularity)$

$$\mu_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n$$

- Where we have defined

$$N_k = \sum_{n=1}^{N} \gamma(z_{nk})$$

- Which is the effective number of points assigned to cluster $k$

Mean of $k^{th}$ Gaussian component is the weighted mean of all the points in the data set: where data point $x_n$ is weighted by the posterior probability that component $k$ was responsible for generating $x_n$
M.L.E. solution for Covariance

- Set derivative w.r.t. $\sum_k$ to zero
  - Making use of mle solution for covariance matrix of single Gaussian
    
    $$
    \Sigma_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk})(x_n - \mu_k)(x_n - \mu_k)^T
    $$

    - Similar to result for a single Gaussian for the data set but each data point weighted by the corresponding posterior probability
    - Denominator is effective no of points in component
**M.L.E. solution for Mixing Coefficients**

- **Maximize** $\ln p(X | \pi, \mu, \Sigma)$ w.r.t. $\pi_k$
  - Must take into account that mixing coefficients sum to one
  - Achieved using Lagrange multiplier and maximizing
    $$\ln p(X | \pi, \mu, \Sigma) + \lambda \left( \sum_{k=1}^{K} \pi_k - 1 \right)$$
  - Setting derivative w.r.t. $\pi_k$ to zero and solving gives
    $$\pi_k = \frac{N_k}{N}$$
Summary of m.l.e. expressions

• GMM maximum likelihood estimates

\[ \mu_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n \]

Parameters (means)

\[ \Sigma_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk})(x_n - \mu_k)(x_n - \mu_k)^T \]

Parameters (covariance matrices)

\[ \pi_k = \frac{N_k}{N} \quad N_k = \sum_{n=1}^{N} \gamma(z_{nk}) \]

Parameters (Mixing Coefficients)

All three are in terms of responsibilities
EM Formulation

- The results for $\mu_k, \Sigma_k, \pi_k$ are not closed form solutions for the parameters
  - Since $\gamma(z_{nk})$ the responsibilities depend on those parameters in a complex way
- Results suggest an iterative solution
- An instance of EM algorithm for the particular case of GMM
Informal EM for GMM

- First choose initial values for means, covariances and mixing coefficients
- Alternate between following two updates
  - Called E step and M step
- In E step use current value of parameters to evaluate posterior probabilities, or responsibilities
- In the M step use these posterior probabilities to re-estimate means, covariances and mixing coefficients
EM using Old Faithful

Data points and Initial mixture model

Initial E step Determine responsibilities

After first M step Re-evaluate Parameters

After 2 cycles

After 5 cycles

After 20 cycles
Comparison with \( K \)-Means

K-means result

E-M result

\[ L = 20 \]
Animation of EM for Old Faithful Data

Code in R

```r
# initial parameter estimates (chosen to be deliberately bad)
theta <- list( tau=c(0.5,0.5),
               mu1=c(2.8,75),
               mu2=c(3.6,58),
               sigma1=matrix(c(0.8,7,7,70),ncol=2),
               sigma2=matrix(c(0.8,7,7,70),ncol=2) )
```
Practical Issues with EM

• Takes many more iterations than $K$-means
• Each cycle requires significantly more comparison
• Common to run $K$-means first in order to find suitable initialization
• Covariance matrices can be initialized to covariances of clusters found by $K$-means
• EM is not guaranteed to find global maximum of log likelihood function
Summary of EM for GMM

• Given a Gaussian mixture model
• Goal is to maximize the likelihood function w.r.t. the parameters (means, covariances and mixing coefficients)

Step1: Initialize the means $\mu_k$, covariances $\Sigma_k$, and mixing coefficients $\pi_k$ and evaluate initial value of log-likelihood
EM continued

• **Step 2:** E step: Evaluate responsibilities using current parameter values

\[
\gamma(z_k) = \frac{\pi_k N(x | \mu_k, \Sigma_k)}{\sum_{j=1}^{K} \pi_j N(x | \mu_j, \Sigma_j)}
\]

• **Step 3:** M Step: Re-estimate parameters using current responsibilities

\[
\mu_k^{\text{new}} = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n
\]

\[
\Sigma_k^{\text{new}} = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk})(x_n - \mu_k^{\text{new}})(x_n - \mu_k^{\text{new}})^T
\]

\[
\pi_k^{\text{new}} = \frac{N_k}{N}
\]

where \( N_k = \sum_{n=1}^{N} \gamma(z_{nk}) \)
EM Continued

- **Step 4:** Evaluate the log likelihood

\[
\ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left( \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right)
\]

- And check for convergence of either parameters or log likelihood

- **If convergence not satisfied return to Step 2**
