Topics in Inference as Optimization

- Overview
- Exact Inference revisited
- The Energy Functional
- Optimizing the Energy Functional
Exact and Approximate Inference

• PGMs represent probability distributions $P_\Phi(\chi)$
  – Where $\chi$ is a set of variables and $\Phi$ is a set of factors

• Inference is the task of answering queries
  – e.g., compute conditional probability $P_\Phi(Y|E=e)$, $Y, E \subseteq \chi$

• Problem of inference in PGMs is $\mathcal{NP}$-hard
  – Worst case is exponential

• *Exact Inference* is often efficient using
  – Variable Elimination or Clique tree Algorithms
    • But complexity is exponential in tree width of network
    • In such cases exact algorithms become infeasible

• This motivates *approximate inference*
Approximate Target Distribution

- We consider approximate inference methods where the approximation arises from constructing an approximation to the target distribution $P_\Phi$.
- This approximation takes a simpler form that allows inference.
- Simpler approximating form exploits factorization structure of PGM.
Principles of Approximate Algorithms

• Approximate inference methods share common conceptual principles:
  1. Find target class $Q$ of “easy” distributions $Q$ and
  2. Then Search for an instance within that class that best approximates $P_\Phi$
  3. Answer queries using inference on $Q$ instead of $P_\Phi$
  4. All methods optimize the same target function for measuring similarity between $Q$ and $P_\Phi$

• This reformulates inference problem as:
  – Optimizing an objective function over class $Q$
Reformulated Inference Problem

• This problem is one of constrained optimization
  – i.e., find distribution $Q$ that minimizes $D(Q \| P_\Phi)$
  – Such problems can be solved by variety of different optimization techniques

• Technique most often used for PGMs is based on Lagrange multipliers

• Constrained optimization and Lagrange solution is discussed next
What is constrained optimization?

- **Ex:** find the maximum entropy distribution over \( X \) with \( Val(X) = \{x_1, \ldots, x^K\} \) where entropy is

\[
H(X) = -\sum_{k=1}^{K} p(x^k) \log p(x^k)
\]

- **Unconstrained Optimization**
  - Use gradient method treating each \( P(x^k) \) as a parameter \( \theta_k \)
    - Compute gradient of \( H_P(X) \) wrt parameters: \[
    \frac{\partial}{\partial \theta_k} H(X) = -\log(\theta_k) - 1
    \]
    - Setting partial derivative to 0 we get \( \log(\theta_k) = 1 \), or \( \theta_k = 1/2 \)
    - But nos do not add up to 1, and hence not a distribution
    - Flaw in analysis: we want constraints that \( \sum_k \theta_k = 1 \), and \( \theta_k \geq 0 \)

- **Constrained Optimization**
  - Maximizing a function \( f \) under equality constraints
    - Find \( \theta \)
    - Maximizing \( f(\theta) \)
    - Subject to \( c_1(\theta) = 0 \)
      - \( \ldots \)
      - \( c_m(\theta) = 0 \)
    
Method of Lagrange multipliers allows us to solve constrained optimization problems using tools for unconstrained optimization. Lagrangian is

\[
J(\theta, \lambda) = f(\theta) - \sum_{j=1}^{m} \lambda_j c_j(\theta)
\]
Lagrange leads to Message Passing

- Method of Lagrange multipliers produces a set of equations that characterize the optima of the objective
- It produces a set of fixed-point equations that define each variable in terms of others
- Fixed point equations derived from constrained energy optimization can be viewed as passing messages over a graph object
Categories of methods in this class

1. Message passing on Clique Tree
   - Loopy belief propagation
     • Optimize approximate versions of the energy functional

2. Message passing on Clique Trees with approximate messages
   - Called expectation propagation
     • Maximize exact energy functional but with relaxed constraints on $Q$

3. Mean-field method
   - Originates in statistical physics
     • Focus on $Q$ that has simple factorization
Examples of Clique Tree

Bayesian Network 1

Moralized Graph and Clique tree

Bayesian Network 2

Moralized Graph

Clique tree

Triangulation

Cluster Graph
Calibrated Clique Tree

1. Gibbs Distribution

\[
\tilde{P}_\phi(A, B, C, D) = \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A)
\]

Unnormalized Measure

\[
P(A, B, C, D) = \frac{1}{Z} \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A)
\]

where

\[
Z = \sum_{A, B, C, D} \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A)
\]

\[Z = 7,201,840\]

2. Clique Tree (triangulated):

**Initial Potentials:**

**Beliefs:**

Clique Beliefs

\[
\beta_1(A, B, D) = \sum_C \psi_1(A, B, D) = \sum_C \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A)
\]

e.g., \(\beta_1(a^0, b^0, d^0) = 100 + 100 = 200\)

\[
\beta_2(B, C, D) = \sum_A \psi_2(B, C, D) = \sum_A \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A)
\]

e.g., \(\beta_2(b^0, c^1, d^0) = 300,000 + 100 = 300,100\)

Sepset Beliefs

\[
\mu_{12}(B, D) = \sum_{C_1 \in S_{1,2}} \beta_1(C_1) = \sum_A \beta_1(A, B, D)
\]

e.g., \(\mu_{12}(b^0, d^0) = 600,000 + 200 = 600,200\)

**Measure induced by calibrated tree \(T\)**

\[
Q_T = \prod_{C_i \in T} \beta_i(C_i) = \prod_{C_i \in T} \mu_{12}(C_i)
\]

where \(\mu_{12} = \sum_{C_i \in S_{1,2}} \beta_i(C_i) = \sum_{C_i \in S_{1,2}} \beta_i(C_i)\)

E.g., \(\tilde{P}_\phi(a^1, b^0, c^1, d^0) = 100\) and measure induced is

\[
\frac{200 \cdot 300}{600 \cdot 200} = \frac{60,000}{120,000} = 100
\]
Belief Propagation

A simple network       A Clique Tree         A Cluster Graph

- Clique tree and cluster graph are alternative ways of doing inference
- Cluster graph may contain loops
- Inference is Called *Loopy Belief Propagation*
- Clusters are smaller than in Clique Tree
Exact Inference Revisited

• We have a factorized distribution of the form

\[ P_\Phi(X) = \frac{1}{Z} \prod_{\phi \in \Phi} \phi(U_\phi) \]

– where \( U_\phi = \text{Scope} (\phi) \)

– Factors are:
  • CPDs in a BN or
  • potentials in a MN

• We are interested in answering queries:
  – about marginal probabilities of variables and
  – about the partition function
Cluster Graph Representation

- End-product of Belief Propagation is a calibrated cluster tree
  - A calibrated set of beliefs represents a distribution
- We view exact inference as searching over the set of distributions $Q$ that are representable by the cluster tree to find a distribution $Q^*$ that matches $P_\Phi$

Cluster graph $U$ for factors $\Phi$ over $\chi$ is an undirected graph

Each of whose nodes $i$ is associated with a subset
Each edge between pair of clusters $C_i$ and $C_j$ is associated with a sepset $S_{i,j} \subseteq C_i \cap C_j$

A tree $T$ is a clique tree for graph $\mathcal{H}$ if

- Each node in $T$ corresponds to a clique in $\mathcal{H}$ and each maximal clique in $\mathcal{H}$ is a node in $T$
- Each sepset $S_{i,j}$ separates $W_{<(j,j)}$ and $W_{<(j,i)}$ in $\mathcal{H}$
Distance between $Q$ and $P_\Phi$

- We need to optimize distance between $Q$ and $P_\Phi$ without answering hard queries about $P_\Phi$
- **Relative entropy** (or K-L divergence) allows us to exploit the structure of $P_\Phi$ without performing reasoning with it
  
  - **Relative entropy** of $P_1$ and $P_2$ defined as
  
  $$D(P_1 \parallel P_2) = E_{P_1} \left[ \frac{\ln P_1(\chi)}{\ln P_2(\chi)} \right]$$
  
  - It is always non-negative
  - Equal to 0 if and only if $P_1 = P_2$

  - We search for distribution $Q$ that **minimizes** $D(Q \parallel P_\Phi)$
Specifying the set $Q$

• We need to specify objects to optimize over

• Suppose we are given:
  
  – a clique tree structure $T$ for $P_{\Phi}$,
  
  – a set of beliefs $Q = \{\beta_i : i \in V_T\} \cup \{\mu_{i,j} : (i,j) \in E_T\}$

  where $C_i$ are clusters in $T$,
  
  $\beta_i$ denote beliefs over $C_i$ and
  
  $\mu_{i,j}$ denotes beliefs $S_{i,j}$ of edges in $T$

• Set of beliefs in $T$ defines a distribution $Q$ by

  $$Q(\chi) = \frac{\prod_{i \in V_T} \beta_i}{\prod_{(i,j) \in E_T} \mu_{i,j}}$$

  The beliefs correspond to marginals of $Q$

  $\beta_i[c_i] = Q(c_i)$

  $\mu_{ij}[s_{ij}] = Q(s_{ij})$

• We are now searching over a set of distributions $Q$

  – that are representable by a set of beliefs $Q$ over the cliques and sepsets in a particular clique tree structure $T$
Statement of Inference as Optimization

- Exact inference is one of maximizing \(-D(Q \parallel P_\Phi)\) over the space of calibrated sets \(Q\)

\[ \text{Ctree-Optimize-KL} \]

- Find \(Q=\{\beta_i; \ i \in V_T\} \cup \{\mu_{i,j}; \ (i,j) \in E_T\}\)
- Maximizing \(-D(Q \parallel P_\Phi)\)
- Subject to

\[
\begin{align*}
\mu_{i,j}[s_{i,j}] &= \sum_{c_{i-s_{i,j}}} \beta_i(c_i) \quad \forall (i-j) \in E_T, \forall s_{i,j} \in \text{Val}(S_{i,j}) \\
\sum_{c_i} \beta_i(c_i) &= 1 \quad \forall i \in V_T
\end{align*}
\]

- **Theorem**: If \(T\) is an I-map of \(P_\Phi\) then there is a unique solution to Ctree-Optimize-KL
Possible approach

• Examine different configurations of beliefs that satisfy marginal consistency constraints
  – Select the configuration that maximizes the objective
  – Such as exhaustive examination is impossible to perform

• Instead of searching over a space of all calibrated trees we can search over a space of simpler distributions
  – We will not find a distribution equivalent to $P_\Phi$ but one that is reasonably close
The Energy Functional

- Directly evaluating $D(Q \parallel P_\Phi)$ is unwieldy
  
  \[
  D(P_1 \parallel P_2) = E_{P_1} \left[ \frac{\ln P_1(\chi)}{\ln P_2(\chi)} \right] = \sum_{\chi} P_1[\chi] \left[ \frac{\ln P_1(\chi)}{\ln P_2(\chi)} \right]
  \]
  - Because summation over all $\chi$ is infeasible in practice

- Instead use equivalent form
  
  \[
  D(Q \parallel P_\Phi) = \ln Z - F(\tilde{P}_\Phi, Q)
  \]
  - Where $F$ is the energy functional

- Theorem:
  
  \[
  F[\tilde{P}_\Phi, Q] = E_Q[\ln \tilde{P}(\chi)] + H_Q(\chi) = \sum_{\phi \in \Phi} E_Q[\ln \phi] + H_Q(\chi)
  \]

- Since the term $\ln Z$ does not depend on $Q$,
  
  - minimizing relative entropy $D(Q \parallel P_\Phi)$ is equivalent to maximizing the energy functional $F(\tilde{P}_\Phi, Q)$

- Energy functional $F[\tilde{P}_\Phi, Q]$ has two terms:
  
  - energy term (expectation of logs of factors in $\Phi$) and
  - entropy term
Optimizing the Energy Functional

• From here onward we pose the problem of finding a good \( Q \) as one of maximizing the energy functional
  – Equivalently minimizing the relative entropy
  – Importantly energy functional involves expectations in \( Q \)
  – By choosing \( Q \) that allow efficient inference we can evaluate/ optimize the energy functional

• Moreover, energy Functional is a lower bound on partition function
  – Since \( D(\mathcal{Q}||\mathcal{P}_\Phi) \geq 0 \) we have \( \ln Z \geq F[\tilde{\mathcal{P}}_\Phi, Q] \)
  – Useful since partition function is usually the hardest part of inference
    • Plays important role in learning
Strategies for optimizing energy functional

• Methods are referred to as *Variational Methods*
• Refers to a strategy in which we introduce new parameters that increase the degrees of freedom
• Each choice of these parameters gives a different approximation
• We attempt to optimize the variational parameters to get the best approximation
• *Variational calculus*: finding optima of a functional
  – E.g., distribution that maximizes entropy
Further Topics in Variational Methods

- Exact Inference
- Propagation-Based Approximations
- Propagation with Approximate Messages
- Structured Variational Approximations
