Local Probabilistic Models: Context-Specific CPDs

Sargur Srihari
srihari@cedar.buffalo.edu
Topics

- Context-Specific CPDs
  1. Regularity in parameters for different values of parents
  2. Tree CPDs
  3. Rule CPDs
  4. Multinets
  5. Similarity Networks
Context-Specific CPDs

• Deterministic dependency is one example of structure in CPDs

• A very common type of regularity arises when we have the same effect in several contexts
  – Several different distributions are the same

• Example is given next
Augmented Student BN: Regularity

- **Model event:** offered a job at Acme Consulting

  - **New binary variable** \( \text{Job} \)
    - \( j^1 \): offered job, \( j^0 \): otherwise
  - Job depends on \( SAT \) & \( Letter \)
  - Student may \( Apply \): \( a^1 \), or not \( a^0 \)

- **We need to describe CPD:** \( P(J|A,S,L) \)

  - Recruiter is desperate to offer job even without applying
    - If \( A=a^0 \), no access to \( L \) and \( S \). So, among 8 values of parents \( A,S,L \), four with \( A=a^0 \) induces identical distributions over variable \( J \)
  - Recruiter feels \( SAT \) more important than letter
    - High \( SAT \) generates offer without letter: \( P(J|a^1,s^1,l^1) = P(J|a^1,s^1,l^0) \)
    - Low \( SAT \) requires letter

- **Several values of** \( Pa_J \) specify same conditional probability over \( J \). We need 8 parameters here.
Representing regularity in CPDs

• We have seen several values of $P_{a,J}$ specify the same conditional probability over $J$

• How to capture this regularity in our CPD representation

• Many approaches for capturing functions over a scope $X$ that are constant over subsets of instantiations to $X$
  
  – Trees
  
  – Rules
Tree-CPD

• Naturally captures common elements in a CPD
  – Tree for $P(J|A,S,L)$
  – Internal nodes represent tests
    • on parent variables
  – Leaves are annotated with distribution over $J$
    – $P(a^0)=0.2$, i.e., probability of offer without applying
    – To determine $P(J|a^1,s^1,l^0)$:
      i.e., student applies, has good SAT letter immaterial
      • choose path $A=a^1$ and $S=s^1$
      • $P(j^0)=0.1$, $P(j^1)=0.9$
    – Which is what we use for $P(J|a^1,s^1,l^0)$
      Need 4 parameters instead of 8 in table
Definition of Tree CPD

• A tree-CPD for a variable \( X \) is a rooted tree
• Each t-node in the tree is either a leaf t-node or an interior t-node
• Each leaf is labeled with a distribution \( P(X) \)
• Each interior node is labeled with some variable \( Z \in Pa_X \)
• Each interior node has a set of arcs to its children each one associated with a unique assignment \( Z = z_i \) for \( z_i \in Val(Z) \)
• **George** has to decide whether to give the recruiter the letter from the Professor of CSE 674 or the Professor of CSE 601

• Depending on which choice **George** makes the dependence will only be on one of the two
Multiplexer CPD

- A CPD $P(Y|A,Z_1,..Z_k)$ is a multiplexer CPD if $\text{Val}(A)=\{1,..,k\}$ and $P(Y|a,Z_1,..,Z_k)=1\{Y=Z_a\}$
  - Where $a$ is the value of $A$
  - The variable $A$ is called the selector variable of the CPD

- In other words, the value of the selector variable is a copy of the value of one of its parents
  - The role of $A$ is to select the parent who is being copied
(a) network fragment
(b) tree CPD for \( P(\mathcal{J}|C,L_1,L_2) \)
(c) Modified network with new variable \( L \) that has a multiplexer CPD
Advantage of Trees

• Provide natural framework for representing context-specificity in a CPD
• People find it convenient
• Lends itself well to automated learning algorithms
  – To construct a tree automatically from a data set
Tree Application: Diagnostic Networks

- Trouble-shooting of physical systems
- Context specificity is due to presence of alternative configurations
- Diagnosis of faults in a printer
  - Part of trouble-shooting network for MS Windows 95
  - Printer can be hooked up to either network via
    - Ethernet cable (*Network transport medium*)
      - Affects printer output only if printer is hooked to network
    - Or to local computer via cable (*Local Transport medium*)
Context-Specific Dependencies

(a) Real-world BN for Microsoft Online Trouble-shooting system

(b) Structure of Tree-CPD for Printer Output variable

Reduces no. of parameters required from 145 to 55
Rule CPD

- Trees capture entire CPD in a single data structure
- A finer-grained specification is via rules
  - Each rule corresponds to a single entry in the CPD of the variable
  - A rule $\rho$ is a pair $(c; p)$
    - where $c$ is an assignment to some subset of variables $C$ and $p \in [0,1]$.
    - $C$ is the scope of $\rho$ denoted $\text{Scope}[^\rho]$.
- This representation decomposes a tree-CPD into its most basic elements
Ex: Tree CPD for $p(J|A,S,L)$

- There are 8 entries in the CPD tree
- Such that each one corresponds to a branch in the tree and an assignment to the variable $J$ itself
- Thus the CPD defines eight rules
Ex: Rule CPD for $p(J|A,S,L)$

- There are 8 entries in the CPD tree
  - Such that each one corresponds to a branch in the tree and an assignment to the variable $J$ itself
  - Thus the CPD $P(J|A,S,L)$ is defined by eight rules
- A formal definition of rule-based CPDs follows
Definition of Rule-based CPD

- A rule-based CPD $p(X|Pa_X)$ is a set of rules $R$ such that
  - For each rule $\rho \in R$ we have that
    \[
    \text{Scope}[\rho] \subseteq \{X\} \cup Pa_X
    \]
  - For each assignment $(x,u)$ to $\{X\} \cup Pa_X$ we have precisely one rule $(c;\rho) \in R$ such that
    \[c\] is compatible with $(x,u)$.
  - In this case we say that $P(X=x|Pa_X=u)=p$

- The resulting CPD $P(X|U)$ is a legal CPD in that
  \[
  \Sigma_x P(x|u)=1
  \]
Other Representations

- Tree and rule representations are useful for representation, inference and learning.
- However other representations are possible.
- They both induce partitions of $\{X\} \cup \text{Pa}_X$ defined by branches of the tree or rule contexts.
  - Each partition is associated with a different entry in $X$’s CPD.
- Other such methods are decision diagrams, multinets and similarity networks.
Multinets

• A more global approach to specifying context-specific independence

• A simple multinet
  – A network centered on a single class variable $C$, which is the root of the network
  – The multinet defines a separate network $B_c$, for each value of $C$
  – The structure and parameters can differ for these different networks
Common form of multinet

• A single network where every variable $X$ has as its parents:
  – $C$ and all variables $Y$ in any of the networks $B_c$

• However the CPD of $X$ is such that in context $C=c$ it depends only on $Pa^B_c$
A subtlety in multinet

• In some cases a subtlety arises where $Y$ is a parent of $X$ in $B_{c^1}$ and $X$ is a parent of $Y$ in $B_{c^2}$
• In this case the BN induced by the multinet is cyclic,
  – Nevertheless, because of context specific independence properties of this network, it specifies a coherent distribution
Usefulness of multinet

- Although a multinet can be represented as a standard BN with context-specific CPDs, it is nevertheless useful.
- Since it explicitly shows the independencies in a graphical form, making them easier to understand and elicit.
Similarity Network

- Related to the multinet representation
- In a similarity network we define a network $B_S$ for certain subsets of values $S \subseteq \text{Val}(C)$ which contain only those attributes relevant for distinguishing between values in $S$
  
  - The underlying assumption is that if a variable $X$ does not appear in network $B_S$ then $P(X|C=c)$ is the same for all $c \in S$
  
  - Moreover if $X$ does not appear in the network $B_S$ then $X$ is contextually independent of $Y$ given $C \in S$ and $X$'s other parents in this network
