Topics

• Design patterns for RNNs
• RNN with recurrence between hidden units
• Forward propagation equations
• Loss function for a sequence
• RNN with recurrence from output units to hidden units
• Teacher forcing for output-to-hidden RNNs
• Backward Propagation through time (BPTT)
Three design patterns of RNNs

1. Produce output at each time step and have recurrent connections between hidden units

2. Produce output at each time step and have recurrent connections only from output at one time step to hidden units at next time step
   - Less powerful than (1) but easier to train
     - Each step can be trained in isolation
     - Greater parallelization during training

3. Recurrent connections between hidden units that read an entire input sequence and produce a single output
   - Can summarize a sequence and produce a fixed size representation for further processing
RNN with recurrence between hidden units

- Maps input sequence $\mathbf{x}$ to output $\mathbf{o}$ values
  - Loss $L$ measures how far each $\mathbf{o}$ is from the corresponding target $\mathbf{y}$
    - With softmax outputs we assume $\mathbf{o}$ is the unnormalized log probabilities
    - Loss $L$ internally computes $\mathbf{y} = \text{softmax}(\mathbf{o})$ and compares to target $\mathbf{y}$
  - Update equation

$$ a^{(t)} = b + Wh^{(t-1)} + Ux^{(t)} $$
RNN with hidden unit recurrence is a Universal TM

- RNN with hidden unit connections together with
  
  \[ a^{(t)} = b + Wh^{(t-1)} + Ux^{(t)} \]

  is Universal, i.e.,
  
  - Any function computable by a TM is computable by such an RNN of finite size

- Output can be read from the RNN after no. of steps asymptotically linear in no. of steps used by the TM and asymptotically linear in length of input
Forward prop for RNN with hidden unit recurrence

- This design does not specify
  1. activation functions for hidden units,
  2. form of output and
  3. loss function

- Assume for this graph:
  1. Hyperbolic tangent activation function
  2. Output is discrete
    - E.g., RNN predicts words/characters
    - Natural way to represent discrete vars:
      - Output $o$ gives unnormalized log probabilities $\hat{y}$ of each possible value
      - Can apply $\text{softmax}$ as a postprocessing step to obtain vector of normalized probabilities over the output

- Forward prop begins with specification of initial state $h^{(0)}$
Forward Prop Equations for RNN with hidden recurrence

- Begins with initial specification of $h^{(0)}$
- Then for each time step from $t=1$ to $t=\tau$ we apply the following update equations

\[
\begin{align*}
o^{(t)} &= c + Vh^{(t)} \\
h^{(t)} &= \tanh(a^{(t)}) \\
a^{(t)} &= b + Wh^{(t-1)} + Ux^{(t)} \\
\hat{y}^{(t)} &= \text{softmax}(o^{(t)})
\end{align*}
\]

- Where the parameters are:
  - bias vectors $b$ and $c$
  - weight matrices $U$ (input-to-hidden), $V$ (hidden-to-output) and $W$ (hidden-to-hidden) connections
Loss function for a given sequence

- This is an example of an RNN that maps an input sequence to an output sequence of the same length.
- Total loss for a given sequence for a given sequence of $x$ values with a sequence of $y$ values is the sum of the losses over the time steps.
- If $L^{(t)}$ is the negative log-likelihood of $y^{(t)}$ given $x^{(1)}, \ldots x^{(t)}$ then

$$
L \left( \left\{ x^{(1)}, \ldots x^{(t)} \right\}, \left\{ y^{(1)}, \ldots y^{(t)} \right\} \right) = \sum_{t} L^{(t)}
$$

$$
= - \sum_{t} \log p_{model} \left( y^{(t)} \mid \left\{ x^{(1)}, \ldots x^{(t)} \right\} \right)
$$

- where $p_{model}$ is given by reading the entry for $y^{(t)}$ from the model’s output vector $\hat{y}^{(t)}$. 
Computing Gradient of Loss Function

- Computing gradient of this loss function wrt parameters is expensive
  - It involves performing a forward propagation pass moving left to right through the unrolled graph followed by a backward propagation moving right to left through the graph
- Run time is $O(\tau)$ and cannot be reduce by parallelization
  - Because forward propagation graph is inherently sequential
    - Each time step computable only after previous step
  - States computed during forward pass must be stored until reused in the backward pass
    - So memory cost is also $O(\tau)$
- Backpropagation applied to the unrolled graph with $O(\tau)$ cost is called Backward Propagation through time (BPTT)
Backward Propagation through Time (BPTT)

- RNN with hidden unit recurrence is very powerful but also expensive to train
- Is there an alternative?
RNN with recurrence from output to hidden

- A network with recurrent connections from output (at one time step) to hidden units (at next time step)
- It is strictly less powerful than hidden-to-hidden recurrence
  1. Cannot simulate a universal TM
  2. Because output units are trained to match training set targets, they are unlikely to capture past history of input unless user provides it as part of training set targets
Advantage of eliminating hidden recurrence

- For any loss function based on comparing prediction at time $t$ to training target at time $t$, all time steps are decoupled.
- Training can be parallelized with gradient for each time step $t$ computed in isolation.
- There is no need to compute the output for the previous time step first.
  - Because the training set provides the ideal value of that output.
- Models that have recurrent connections from their outputs leading back to the model may be trained with teacher forcing.
