Topics in Optimization for Deep Models

- Importance of Optimization in machine learning
- How learning differs from optimization
- Challenges in neural network optimization
- Basic Optimization Algorithms
- Parameter initialization strategies
- Algorithms with adaptive learning rates
- Approximate second-order methods
- Optimization strategies and meta-algorithms
Topics in Optimization Strategies and Meta-Algorithms

1. Batch Normalization
2. Coordinate Descent
3. Polyak Averaging
4. Supervised Pretraining
5. Designing Models to Aid Optimization
6. Continuation Methods and Curriculum Learning
Overview: Optimization Strategies

- Many optimization techniques are general templates that can be specialized to yield algorithms
- They can be incorporated into different algorithms
1. Batch Normalization

- An exciting recent innovation
- Motivated by difficulty of training deep models
- Method adds an additional step between layers, in which the output of the earlier layer is normalized
  - By standardizing the mean and standard deviation of each individual unit
- It is a method of adaptive reparameterization
  - It is not an optimization algorithm at all
  - A method to reduce internal covariate shift in neural networks
Motivation: Difficulty of composition

- Very deep models involve compositions of several functions or layers
- The gradient tells us how to update each parameter
  - Under the assumption that other layers do not change
  - We update all the layers simultaneously
  - When we make the change unexpected results can happen
    - Because many functions are changed simultaneously
    - Under the assumption that other functions remain constant
Simple example: Learning rate in multilayer

- \( l \) layers, one unit per layer, no activation fn
  \[ y = xw_1w_2w_3 \ldots w_l, \quad w_i \text{ provides weight of layer } i \]
- Output of layer \( i \) is \( h_i = h_{i-1}w_i \)
  - Output is a linear function of input \( x \) but a nonlinear function of the weights \( w_i \)
- Suppose cost has put a gradient of 1 on \( y \), so we wish to decrease \( y \) slightly
- Backpropagation can compute a gradient \( g = \nabla_w y \)
- Consider update \( w \leftarrow w - \varepsilon g \)
  - First order Taylor’s series approx of \( y \) predicts that the value of \( y \) will decrease by \( \varepsilon g^T g \)
Difficulty of Multilayer learning Rate

• If we wanted to decrease $y$ by 0.1 we could set the learning rate $\varepsilon$ to $0.1/g^Tg$

• The new value of $y$ is $x(w_1-\varepsilon g_1)(w_2-\varepsilon g_2)\ldots(w_l-\varepsilon g_l)$
  – A second order term arising from this update is $\varepsilon^2 g_1 g_2 \prod_{i=3}^{l} w_i$
  – This term can be negligible if $\prod_{i=3}^{l} w_i$ is small or exponentially large if weights on layers 3 to $l$ are greater than 1

• This makes it very hard to choose $\varepsilon$ because the effects the effects of an update for one layer depend so strongly on all other layers

• Second-order optimization algorithms address this issue but it seems hopeless for $l > 2$
The Batch Normalization Solution

• Provides an elegant way of reparameterizing almost any network
• Significantly reduces the problem of coordinating updates across many layers
• Can be applied to any input or hidden layer in a network
Batch Normalization Equations

- Let $H$ be the minibatch of activations of the layer to normalize
  - arranged as a design matrix
    - With activations for each example appearing in a row
- To normalize $H$ we replace it with $H' = \frac{H - \mu}{\sigma}$
- Where $\mu$ is a vector containing the mean of each unit and $\sigma$ is the std deviation of each unit
- Arithmetic based on broadcasting the vector $\mu$ and the vector $\sigma$ to be applied to every row of $H$
- Within each row, the arithmetic is element-wise
  - $H_{i,j}$ is normalized by subtracting $\mu_{i,j}$ & dividing by $\sigma_j$
Normalization Details

• Rest of the network operates on $H'$ in the same way that the original network operated on $H$

• At training time

$$\mu = \frac{1}{m} \sum_i H_i$$

and

$$\sigma = \sqrt{\delta + \frac{1}{m} \sum_i (H - \mu)^2}$$

• where $\delta$ is a small positive value such as $10^{-8}$ imposed to avoid encountering the undefined gradient of $\sqrt{z}$ at $z=0$

– Crucially we back propagate through these operations for computing the mean and std dev

– And for applying them to normalize $H$

• This means that the gradient will never propose an operation that acts simply to increase std dev or mean of $h_i$. The normalization operations remove the effect of such an action and aero out the component in the gradient
Batch Normalization at Test time

• At test time, $\mu$ and $\sigma$ may be replaced by running averages that were collected during training time

• This allows the model to be evaluated on a single example without needing to use definitions of $\mu$ and $\sigma$ that depend on an entire minibatch

• Revisiting the simple example we can mostly resolve the difficulties in learning the model

$$y = x w_1 w_2 w_3 \ldots w_l$$ by normalizing $h_{l-1}$
Revisiting the simple example

• Suppose $x$ is drawn from a Gaussian
  – Then $h_{l-1}$ will also come from a Gaussian, because the transformation from $x$ to $h_l$ is linear
    • However, $h_{l-1}$ will no longer have zero mean, unit variance
  – After batch normalization, we obtain the normalized $h_{l-1}$ that restores zero mean and unit variance
    • For almost any update to the lower layers, $h_{l-1}$ will remain a unit Gaussian
    • Output $y$ may be learned as a simple linear fn $y = w_l h_{l-1}$
  – Learning in this model is now very simple
    • Because parameters at the lower level do not have an effect in most cases
      – Their output is renormalized to a unit Gaussian
Batch Normalization ➜ learning easy

• Without normalization, updates would have an extreme effect of the statistics of $h_{l-1}$

• Batch normalization has thus made this model easier to learn

• In this example the ease of learning came from making the lower layers useless
  – Lower layers not harmful but not beneficial either
    • Because we have normalized-out 1\textsuperscript{st} and 2\textsuperscript{nd} order stats

• In a deep neural network lower levels can perform useful nonlinear transformations
Reintroducing Expressive Power

- Normalizing the mean and standard deviation can reduce the expressive power of the neural network containing that unit.
- To maintain the expressive power replace the batch of hidden unit activations $H'$ with $\gamma H' + \beta$.
  - $\gamma$ and $\beta$ are learned parameters that allow the new variable to have any mean and standard deviation.
- Has different learning dynamics than unnormalized approach.
