Learning Causality

Sargur N. Srihari
University at Buffalo, The State University of New York
USA

IBM Research Labs, Bangalore
January 2014
Plan of Discussion

1. Machine Learning
   - Problem types

2. PGMs
   - Bayesian Networks

3. Causal Models
   - Learning
New Impetus for ML: Big Data

• Moore’s law (Volume)
  – Processing power doubles every 18 months
  – So also world’s digital content (exponential)
    • Daily 2.5 Exabytes ($10^{18}$ or quintillion) data created

• Complex Data (Variety)
  – Social Media: Text (10m tweets/day) and Images
  – Remote sensing, Wireless Networks

• Response (Velocity)
  – Energy (fracking with images, sound, data)
  – Internet Search, Meteorology, Astronomy
Big Data Analytics

• Descriptive Analytics
  – What happened?
    • Models

• Predictive Analytics
  – What will happen?
    • Predict class

• Prescriptive Analytics
  – How to improve predicted future?
    • Intervention
Machine Learning and Big Data Analytics

1. Perfect Marriage
   - Machine Learning
     • Statistical methods with computational considerations

2. Types of problems solved
   - Predictive Classification: Sentiment
   - Predictive Regression: LETOR
   - Collective Classification: Speech, POS, NE
   - Missing Data Estimation: Clustering
   - Intervention, Counter-factual: Causal Models
History of ML

• **First Generation** (1960-1980)
  – Perceptrons, Nearest-neighbor, Naïve Bayes
  – Special Hardware, Limited performance

• **Second Generation** (1980-2000)
  – ANNs, Kalman, HMMs, SVMs
    • HW addresses, speech reco, postal words
  – Difficult to include domain knowledge
    • Black box models fitted to large data sets

• **Third Generation** (2000-Present)
  – PGMs, Fully Bayesian, GP
    • Big Data [Image segment, Text analytics (NE)]
  – Expert prior knowledge with statistical models
Probabilistic Graphical Models

• Representation
  – Directed PGMs
    • Bayesian Networks (BNs)
      – Useful in many real-world domains
  – Undirected PGMs
    • Markov Networks (MNs or MRFs)
      – Simpler Independence/inference (no D-separation)
  – Partially directed models
    • E.g., some forms of conditional random fields

• Inference
  – Probabilistic queries
    • Marginal, Conditional, MAP
BN REPRESENTATION
PGMs aid in reducing Complexity of Joint Distributions

- For Multinomial with $k$ states for each variable
  - Full Distribution requires $k^n - 1$ parameters
    - with $n=6$, $k=5$ need 15,624 parameters

<table>

Bayesian Network

Nodes: random variables,  Edges: influences

Local Models are combined by multiplying them

\[
\prod_{i=1}^{n} p(x_i | \text{parent}_i)
\]

Provides a factorization of joint distribution:

\[
P(x) = P(x_4)P(x_6 | x_4)P(x_2 | x_6)P(x_3 | x_2)P(x_1 | x_2, x_6)P(x_5 | x_1, x_2)
\]

\[\theta: 4 + (3 \times 24) + (2 \times 125) = 326\] parameters

Organized as Six CPTs, e.g.

\[\text{...} \quad \text{...} \quad \text{...} \quad \text{...} \quad \text{...}\]
Complexity of Inference in a BN

• Probability of Evidence

\[ P(E = e) = \sum_{X \setminus E} \prod_{i=1}^{n} P(X_i \mid pa(X_i)) \bigg|_{E=e} \]

Summed over all settings of values for \( n \) variables \( X \setminus E \)

• An intractable problem
  • No of possible assignments for \( X \) is \( k^n \)
  • They have to be counted
  • \#P complete
  • Tractable if tree-width < 25

• Approximations are usually sufficient (hence sampling)
  • When \( P(Y=y \mid E=e) = 0.29292 \), approximation yields 0.3

P: solution in polynomial time
NP: verified in polynomial time
\#P complete: how many solutions
BN PARAMETER LEARNING
Learning Parameters of BN

- Parameters define local interactions
- Straight-forward since local CPDs

\[ G = \{ V, E, \theta \} \]

Max Likelihood Estimate

\[ P(x_5|x_1, x_2) \]

<table>

Bayesian Estimate with Dirichlet Prior

\[ \begin{array}{l}
\theta \sim \text{Dirichlet}(\alpha_1, \ldots, \alpha_k) \\
\alpha_1 = \ldots = \alpha_k = 1
\end{array} \]

\[ O = \{ o_1, \ldots, o_k \} \sim \text{Multinomial}(\theta_1, \ldots, \theta_k) \]

Posterior

\[ \theta|O \sim \text{Dirichlet}(\alpha'_1, \ldots, \alpha'_k) \]

\[ \alpha'_i = \alpha_i + o_i, \text{ for } i = 1, \ldots, k \]
BN STRUCTURE LEARNING
Need for BN Structure Learning

• **Structure**
  – Cannot be easily determined by experts
  – Variables and Structure may change with new data sets

• **Parameters**
  – When structure is specified by an expert
    • Experts cannot usually specify parameters
  – Data sets can change over time
  – Need to learn parameters when structure is learnt
Independence Tests

1. For variables $x_i, x_j$ in data set $\mathcal{D}$ of $M$ samples
   1. Pearson’s Chi-squared ($X^2$) statistic
      \[
      d_{X^2}(\mathcal{D}) = \sum_{x_i,x_j} \left( \frac{M[x_i,x_j] - M \cdot \hat{P}(x_i) \cdot \hat{P}(x_j)}{M \cdot \hat{P}(x_i) \cdot \hat{P}(x_j)} \right)^2
      \]
      Sum over all values of $x_i$ and $x_j$
      - Independence $\Rightarrow d_X(\mathcal{D})=0$, larger value when Joint $M[x,y]$ and expected counts (under independence assumption) differ

2. Mutual Information (K-L divergence) between joint and product of marginals
   \[
   d_I(\mathcal{D}) = \frac{1}{M} \sum_{x_i,x_j} \log \frac{M[x_i,x_j]}{M[x_i]M[x_j]}
   \]
   - Independence $\Rightarrow d_I(\mathcal{D})=0$, otherwise a positive value

2. Decision rule
   \[
   R_{d_I}(\mathcal{D}) = \begin{cases} 
   \text{Accept } d(\mathcal{D}) \leq t & \text{False Rejection probability due to choice of } t \text{ is its p-value} \\
   \text{Reject } d(\mathcal{D}) > t & 
   \end{cases}
   \]
1. Log-likelihood Score for $G$ with $n$ variables

$$score_L(G : \mathcal{D}) = \sum_{\mathcal{D}} \sum_{i=1}^{n} \log \hat{P}(x_i \mid pax_i)$$  
Sum over all data and variables $x_i$

2. Bayesian Score

$$score_B(G : \mathcal{D}) = \log p(\mathcal{D} \mid G) + \log p(G)$$

3. Bayes Information Criterion

– With Dirichlet prior over graphs

$$score_{BIC}(G : D) = l(\hat{\theta}_G : D) - \frac{\log M}{2} Dim(G)$$
Elements of BN Structure Learning

1. Local: Independence Tests
   1. Measures of Deviance-from-independence between variables
   2. Rule for accepting/rejecting hypothesis of independence

2. Global: Structure Scoring
   – Goodness of Network
BN Structure Learning Algorithms

• **Constraint-based**
  - Find structure that best explains determined dependencies
    - Sensitive to errors in testing individual dependencies
      • Koller and Friedman, 2009

• **Score-based**
  - Search the space of networks to find high-scoring structure
  - Since space is super-exponential, need heuristics
    • K2 algorithm((Cooper & Herskovits, 1992)
    • Optimized Branch and Bound (deCampos, Zheng and Ji, 2009)

• **Bayesian Model Averaging**
  - Prediction over all structures
  - May not have closed form, Limitation of $X^2$
    • Peters, Danzing and Scholkopf, 2011
Greedy BN Structure Learning

Consider pairs of variables ordered by $\chi^2$ value
Add next edge if score is increased

$G^* = \{V, E^*, \theta^*\}$
Start Score $s_{k-1}$

$G_{c1} = \{V, E_{c1}, \theta_{c1}\}$
Candidate $x_4 \rightarrow x_5$
Score $s_{c1}$

Choose $G_{c1}$ or $G_{c2}$ depending on which one increases the score $s(D, G)$
evaluate using cross validation on validation set
Branch and Bound Algorithm

• **Score-based**
  – Minimum Description Length
  – Log-loss

• **$O(n \cdot 2^n)$**

• **Any-time algorithm**
  – Stop at current best solution
Causal Models

• Causality:
  – Relation between an event (the *cause*) and a second event (the *effect*), where the second is understood to be a consequence of the first
  – Examples
    • Rain causes mud, Smoking causes cancer, Altitude lowers temperature
Causal BNs

- A and B are causally independent;
- C, D, E, and F are causally dependent on A and B;
- A and B are direct causes of C;
- A and B are indirect causes of D, E and F;
- If C is prevented from changing with A and B, then A and B will no longer cause changes in D, E and F
BN is not necessarily Causal

- BN is only an efficient representation of a joint distribution in terms of conditional distributions
- Several different BNs can represent the same distribution—equivalence class
Causality in Philosophy

• Dream of philosophers
  – Democritus 460-370BC, father of modern science
    • “I would rather discover one causal law than gain the kingdom of Persia”

• Indian philosophy
  – Karma in Sanatana Dharma
    • A person’s actions causes certain effects in current and future life either positively or negatively
Causality in Medicine

• Medical treatment
  – Possible effects of a medicine
    • Right treatment saves lives

• Vitamin D and Arthritis
  – Correlation versus Causation
  – Need for Randomized Correlation Test
Determining Causal Relationships

- Best way: Randomized controlled experiments
  - May be too difficult or immoral to perform
- Want to rely on “observational” data to infer causal relationships
- Current statistical methods are good at determining correlation
  - Correlation hints at causality
Relationships between events

A | B
A Causes B
B Causes A

Common Causes for A and B, which do not cause each other

A = ice cream sales
B = drowning deaths
C = hot summer

Correlation is a broader concept than causation
Examples of Causal Model

- Statement `Smoking causes cancer’ implies an asymmetric relationship:
  - Smoking leads to lung cancer, but
  - Lung cancer will not cause smoking
- Arrow indicates such causal relationship
- No arrow between smoking and `Other causes of lung cancer’
  - Means: no direct causal relationship between them
Probabilistic Causality

– Deterministic causation
  • If $A$ causes $B$, then $A$ must always be followed by $B$.
    – War does not cause deaths, nor does smoking cause cancer.

– Probabilistic causation
  • $A$ probabilistically causes $B$ if $A$‘s occurrence increases the probability of $B$
    – Smoking causes cancer
  • Reflects either imperfect knowledge of a deterministic system or system under study is inherently probabilistic, such as quantum mechanics
Inference with Causal Networks

1. Probabilistic Queries
   – Similar to other PGMs

2. Intervention Queries
   – Ideal with no other effect
     • If patient takes this medication what are chances of getting well $P(H|\text{do}(M=m_1))$
       – Where H=Health. Which is different from $P(H|m_1)$
         » Patients taking meds on their own are healthier

3. Contra-factual Queries
   • Would the accident have happened if driver was not drunk?
CAUSAL STRUCTURE LEARNING
Statistical Modeling of Cause-Effect

Data: National Climate Data Center (546 stations)
Additive Noise Model

- Test if variables $x$ and $y$ are independent
- If not test if $y = f(x) + e$ is consistent with data
  - Where $f$ is obtained by nonlinear regression
- If residuals $e = y - f(x)$ are independent of $x$ then accept $y = f(x) + e$. If not reject it.
- Similarly test for $x = g(y) + e$
- If both accepted or both rejected then need more complex relationship
Regression and Residuals

- Residuals more dependent upon temperature
  - $p$ value: forward model = 0.0026
  - backward model = $5 \times 10^{-12}$
- Admit altitude $\rightarrow$ temperature
Justifying additive noise model

- Algorithmic Information Theory
  - Also called Kolmogorov Complexity
- True causal description has a shorter description
Forward and Inverse Problems

• Kinematics of a robot arm

Forward problem: Find end effector position given joint angles
Inverse kinematics: two solutions: Elbow-up and elbow-down
Has a unique solution

• Forward problems correspond to causality in a physical system
  have a unique solution
  e.g., symptoms caused by disease
• If forward problem is a many-to-one mapping, inverse has multiple solutions
Regression Problems

Forward problem data set

Red curve is result of fitting a two-layer neural network by minimizing sum-of-squared error

Corresponding inverse problem by reversing $x$ and $t$

Very poor fit to data: GMMs used here
A Causal BN Structure Learning Algorithm*

- Construct PDAG by removing edges from complete undirected graph
- Use $X^2$ test to sort dependencies
- Orient most dependent edge using additive noise model
- Apply causal forward propagation to orient other undirected edges
- Repeat until all edges are oriented

Conclusion

1. Big Data
   – Scientific Discovery, Most Advances in Technology

2. Machine Learning
   – Methods suited to Analytics: Descriptive, Predictive

3. Causal Models
   – Scientific discovery, Prescriptive Analytics
